4.7	Tannaka duality	116

Preface

These lecture notes were prepared for the graduate course Algebra I from September 2019 to January 2020 at the University of the Chinese Academy of Sciences. We have followed more or less closely notes of Wen-Wei Li [L3] and Yongquan Hu [H2], who taught the course in previous years. I am deeply indebted to them for sharing their notes. I thank Zhijian Chen, Zhibin Geng, Peng Shan, and Hu Tan for corrections and suggestions.

Chapter 1

Fields and Galois theory

Convention 1.0.1. Rings are assumed to have identities and ring homomorphisms are assumed to preserve the identities. Some authors, notably Noether, do not follow this convention.

1.1 Fields and field extensions

Definition 1.1.1. A *field* is a nonzero commutative ring whose nonzero elements are invertible.

Lemma 1.1.2. (1) A commutative ring A is a field if and only if 0 is a maximal ideal A .

(2) Let F be a field and R a nonzero ring. Then every ring homomorphism $\iota: F \rightarrow R$ is an injection.

Proof. (1) Indeed,

$$\begin{aligned} A \text{ is a field} &\Leftrightarrow A \text{ is nonzero and } aA = A \text{ for every nonzero } a \in A \\ &\Leftrightarrow A \text{ is nonzero and the only ideals are } 0 \text{ and } A \\ &\Leftrightarrow 0 \text{ is a maximal ideal of } A. \end{aligned}$$

(2) The kernel of ι is an ideal of F not containing 1, and thus must be zero by (1). \square

In particular every ring homomorphism $\iota: F \rightarrow E$ of fields is an *embedding*. The embedding ι factorizes as $F \simeq \iota(F) \subseteq E$, where $F \simeq \iota(F)$ is an isomorphism (of fields, namely of rings). Given an inclusion of fields $F \subseteq E$ (preserving 1), F is called a *subfield* of E and E is called a (field) *extension* of F , and we adopt the notation E/F (not to be confused with quotient). We sometimes extend the terminology of field extensions to field embeddings.

Recall the *characteristic* of a ring R is the number $n \in \mathbb{Z}_{\geq 0}$ such that $\ker(\mathbb{Z} \rightarrow R) = n\mathbb{Z}$. The characteristic of a field is 0 or a prime number. A *prime field* is a field not containing any proper subfield. It is uniquely isomorphic to \mathbb{Q} or $\mathbb{F}_p = \mathbb{Z}/p\mathbb{Z}$ for some prime number p . Every field F admits a smallest subfield of F , called the prime field of F . For any field embedding $F \hookrightarrow E$, F and E have the same characteristic.

Given a field extension E/F and a subset $S \subseteq E$, there exists a smallest subring $F[S] \subseteq E$ containing F and S . This is a commutative domain and its fraction field $F(S) \subseteq E$ is the smallest subfield containing F and S , called the subfield obtained by *adjoining* S to F or the subfield *generated* by S over F .

Given field extensions K/F and K/F' , the smallest subfield $E \subseteq K$ containing F and F' is called the *composite* of F and F' in K and denoted by $F \cdot F'$ (or FF'). More generally, given a family of field extensions, $(K/F_i)_{i \in I}$, the smallest subfield $E \subseteq K$ containing the F_i 's is called the *composite* of $(F_i)_{i \in I}$ in K and denoted by $\bigvee_{i \in I} F_i$. We have

$$\bigvee_{i \in I} F_i = \bigcup_{J \subseteq I} \bigvee_{j \in J} F_j$$

where J runs through finite subsets of I .

Warning 1.1.3. Given field embeddings $\iota: F \hookrightarrow K$, $\iota': F \hookrightarrow K$, the composite $\iota(F) \cdot \iota'(F')$ depends on the choice of ι , ι' , and K . See Example 1.2.9 below.

Given a field extension E/F , E is an F -vector space.

Definition 1.1.4. The *degree* of a field extension E/F is $[E : F] = \dim_F(E)$ (a cardinal number). A field extension is said to be *finite* if $[E : F]$ is finite.

Lemma 1.1.5. *Let $K/E/F$ be a tower of field extensions.*

- (1) *We have $[K : F] = [K : E][E : F]$ (as cardinal numbers). More precisely, if $(a_i)_{i \in I}$ is a basis for K/E and $(b_j)_{j \in J}$ is a basis for E/F , then $(a_i b_j)_{(i,j) \in I \times J}$ is a basis for K/F .*
- (2) *K/F is finite if and only if both K/E and E/F are finite.*

Proof. (1) Every element $x \in K$ can be written uniquely as $x = \sum_{i \in I} c_i a_i$ with $c_i \in E$ and each c_i can be written uniquely as $c_i = \sum_{j \in J} c_{i,j} b_j$ with $c_{i,j} \in F$. Thus we have a unique expression

$$x = \sum_{(i,j) \in I \times J} c_{i,j} a_i b_j.$$

(2) follows from (1). □

1.2 Simple extensions

A field extension K/F generated by one element $\alpha \in K$ is called a *simple* extension. The element α is called a *primitive* element of K/F .

Definition 1.2.1. Let E/F be a field extension and let $\alpha \in E$. We say that α is *algebraic* over F if there exists a nonzero polynomial $P \in F[X]$ such that $P(\alpha) = 0$. Otherwise we say that α is *transcendental* over F .

Example 1.2.2. $\sqrt[3]{2}, i \in \mathbb{C}$ are algebraic over \mathbb{Q} . It is well known that $e, \pi \in \mathbb{R}$ are transcendental over \mathbb{Q} .

Consider the ring homomorphism $h_\alpha: F[X] \rightarrow E$ carrying X to α , which induces an isomorphism $F[X]/\ker(h_\alpha) \xrightarrow{\sim} F[\alpha]$. By definition, α is algebraic if and only if $\ker(h_\alpha)$ is nonzero. In this case, since $F[X]$ is a PID (principal ideal domain) and $F[X]^\times = F^\times$, $\ker(h_\alpha) = (P(X))$ for a unique monic polynomial $P(X)$. Since $\ker(h_\alpha)$ is a prime ideal, $P(X)$ is irreducible. We call $P(X)$ the *minimal polynomial* of α over F .

Proposition 1.2.3. *Let E/F be a field extension and let $\alpha \in E$.*

- (1) *If α is algebraic over F of minimal polynomial $P(X)$, then h_α induces an isomorphism $F[X]/(P(X)) \xrightarrow{\sim} F[\alpha]$. In this case $F[\alpha] = F(\alpha)$, and $[F(\alpha) : F] = \deg(P)$.*
- (2) *If α is transcendental over F , then h_α induces isomorphisms $F[X] \xrightarrow{\sim} F[\alpha]$ and $F(X) \xrightarrow{\sim} F(\alpha)$. In this case $F(\alpha)/F$ is infinite.*

In particular, α is algebraic over F if and only if $F(\alpha)/F$ is a finite extension.

Proof. (1) The first sentence is clear. Note that $(P(X))$ is a maximal ideal, $F[\alpha]$ is a field, so that $F[\alpha] = F(\alpha)$. Let $d = \deg(P)$. Then $1, \alpha, \dots, \alpha^{d-1}$ form a basis for $F(\alpha)/F$.

(2) The first sentence is clear. For the second sentence, note that $1, \alpha, \alpha^2, \dots$ are F -linearly independent. □

Part (1) has the following converse.

Proposition 1.2.4. *Let F be a field and let $P(X) \in F[X]$ be a monic irreducible polynomial. Then there exists a simple field extension $F(\alpha)/F$ such that $P(X)$ is the minimal polynomial of α over F .*

Proof. We take α to be the image of X in $F[X]/(P(X))$. □

Definition 1.2.5. Let E/F and E'/F be field extensions. An embedding $E \hookrightarrow E'$ (resp. isomorphism $E \xrightarrow{\sim} E'$) whose restriction to F is an identity is called an F -embedding (resp. F -isomorphism).

The simple extension in the above proposition is unique up to (not necessarily unique) F -isomorphism by the following.

Proposition 1.2.6. *Let $F(\alpha)/F$ be a field extension with α algebraic and let $P(X) \in F[X]$ be the minimal polynomial of α . Let E/F be a field extension and let $\beta \in E$ be a root of $P(X)$. Then there exists a unique F -embedding $\iota: F(\alpha) \rightarrow E$ carrying α to β . Moreover, ι induces an isomorphism $F(\alpha) \xrightarrow{\sim} F(\beta)$.*

Proof. The uniqueness is clear. For the existence, it suffices to take $\iota = \iota_\beta \iota_\alpha^{-1}$, where $\iota_\alpha: F[X]/(P(X)) \xrightarrow{\sim} F(\alpha)$ and $\iota_\beta: F[X]/(P(X)) \xrightarrow{\sim} F(\beta)$. □

More on algebraic elements

Remark 1.2.7. Let $K/E/F$ be a tower of field extensions and $\alpha \in K$ algebraic over F . Then α is algebraic over E and $[E(\alpha) : E] \leq [F(\alpha) : F]$. In fact, if $P(X) \in F[X]$ denotes the minimal polynomial of α over F , then $P(\alpha) = 0$ so that the minimal polynomial of α over E divides $P(X)$.

Proposition 1.2.8. *Let $K/E/F$ and $K/E'/F$ be two factorizations with $[E' : F]$ finite. Then $[E \cdot E' : E] \leq [E' : F]$.*

Proof. If a_1, \dots, a_d form an F -linear basis, then $E' = F(a_1, \dots, a_d)$. Let $F_i = F(a_1, \dots, a_i)$ and $E_i = E(a_1, \dots, a_i)$. By the Remark 1.2.7, a_i is algebraic over F_{i-1} and $[E_i : E_{i-1}] \leq [F_i : F_{i-1}]$, and we conclude by induction. \square

Example 1.2.9. Let $\mathbb{Q} \subseteq E \subseteq \mathbb{C}$ where $E = \mathbb{Q}(\sqrt[3]{2})$ and let $\iota : E \hookrightarrow \mathbb{C}$ be the embedding carrying $\sqrt[3]{2}$ to $\omega\sqrt[3]{2}$, where $\omega = e^{2\pi i/3}$ is a primitive cube root of unity. Then $2 = [E \cdot \iota(E) : E] < [\iota(E) : F] = 3$. (Note that $\iota(E) \neq E$ because $E \subseteq \mathbb{R} \not\subseteq \iota(E)$.)

Proposition 1.2.10. *Let E/F be a field extension. Then the set of elements $\alpha \in E$ algebraic over F form a subfield of E . In other words, if $\alpha, \beta \in E$ are algebraic over F , then $\alpha + \beta$, $\alpha\beta$, and α^{-1} (if $\alpha \neq 0$) are algebraic over F .*

Proof. Indeed, $F(\alpha)/F$ is finite and $F(\alpha, \beta)/F(\alpha)$ is finite by Remark 1.2.7. Thus $F(\alpha, \beta)/F$ is finite, so that every $\gamma \in F(\alpha, \beta)$ is algebraic over F . \square

Finitely generated extensions

Definition 1.2.11. A field extension E/F is said to be *finitely generated* if there exists a finite subset $S \subseteq E$ such that $E = F(S)$.

Given a tower of field extensions $K/E/F$ with F/E and E/K finitely generated, then K/F is finitely generated: $F(S_1)(S_2) = F(S_1 \cup S_2)$. We will see later that the converse also holds (Proposition 1.18.20). Let $K/E/F$ and $K/E'/F$ be two factorizations with E'/F finitely generated. Then $E \cdot E'/E$ is finitely generated: $E \cdot F(S) = E(S)$. In particular, if E/F and E'/F are finitely generated, then $E \cdot E'/F$ is finitely generated.

Warning 1.2.12. Finite generation as a field extension is not the same as finite generation as a commutative algebra. For example, $F(X)$ is a finitely-generated field extension of F , but not a finitely-generated commutative F -algebra. One can show (by Noether normalization) that a field extension E/F is finite if and only if E is a finitely-generated commutative F -algebra.

1.3 Algebraic extensions

Definition 1.3.1. We say that a field extension E/F is *algebraic* if every $\alpha \in E$ is algebraic over F . Otherwise we say that E/F is *transcendental*.

Note that $F(\alpha)/F$ is algebraic if and only if α is algebraic. Indeed, the “only if” part is trivial and the “if” part follows from the last assertion of Proposition 1.2.3.

Proposition 1.3.2. *Let E/F be a field extension. Then E/F is finite if and only if it is algebraic and finitely generated.*

Proof. We have already seen that if E/F is finite and a_1, \dots, a_d form an F -linear basis, then each $\alpha \in E$ is algebraic over F and $E = F(a_1, \dots, a_d)$. Conversely, if $E = F(a_1, \dots, a_n)$ with a_i algebraic over F , we have seen that F_i/F_{i-1} is finite, where $F_i = F(a_1, \dots, a_i)$. \square

Proposition 1.3.3. *Let E/F be an algebraic extension. Then every F -endomorphism of E is an F -automorphism.*

Proof. Let $\iota: E \rightarrow E$ be an F -endomorphism and let $x \in E$. Let $P(X) \in F[X]$ be the minimal polynomial of x and let S be the set of roots of P in E . Then ι permutes S . Thus $x \in S$ is in the image of ι . \square

Proposition 1.3.4. (1) *Let $K/E/F$ be a tower of field extensions. Then K/F is algebraic if and only if both K/E and E/F are algebraic.*

(2) *Let $K/E/F$ and $K/E'/F$ be two factorizations with E'/F algebraic. Then $E \cdot E'/E$ is algebraic.*

(3) *Let $K/E_i/F$, $i \in I$ be a family of factorizations with E_i/F algebraic. Then $\bigvee_{i \in I} E_i/F$ is algebraic.*

Proof. (1) The “only if” part is trivial. Conversely, if E/F is algebraic and α is algebraic with minimal polynomial $P(X) = \sum_{i=0}^d a_i X^i$ over E , then α is algebraic over $E_0 = F(a_0, \dots, a_d)$, which is finite over F , so that $F(\alpha) \subseteq E_0(\alpha)$ is finite over F .

(2) $E \cdot E' = E(E')$ is algebraic over E by Proposition 1.2.10.

(3) We may assume that I is finite. By induction, we then reduce to the case $I = \{1, 2\}$, which follows from (1) and (2). \square

Definition 1.3.5. (1) Let E/F be a field extension. We say that F is *algebraically closed in E* if there is no algebraic subextension of E/F other than F .

(2) We say that a field F is *algebraically closed* if there is no algebraic extension of F other than F itself.¹

Let E/F be a field extension. The elements $\alpha \in E$ algebraic over F form a field E_{alg} , called the *algebraic closure of F in E* . Note that E_{alg}/F is algebraic and E_{alg} is algebraically closed in E by Proposition 1.3.4 (1).

Remark 1.3.6. Let F be a field. The following conditions are equivalent:

(1) F is algebraically closed.

(2) Every polynomial $P(X) \in F[X]$ of degree ≥ 1 has a root in F .

(3) Every polynomial $P(X) \in F[X]$ of degree ≥ 1 splits into linear factors.

Indeed, (1) \Leftrightarrow (2) \Leftrightarrow (3).

Let E/F be a field extension with E algebraically closed. Then the algebraic closure E_{alg} of F in E is algebraically closed. Indeed, if $P(X) \in E_{\text{alg}}[X]$ is a polynomial of degree ≥ 1 , then it admits a root $\alpha \in E$. Since α is algebraic over E_{alg} , we have $\alpha \in E_{\text{alg}}$.

Theorem 1.3.7 (Fundamental Theorem of Algebra). *The field \mathbb{C} of complex numbers is algebraically closed.*

¹In French, (1) is *algébriquement fermé* while (2) is *algébriquement clos*.

Definition 1.3.8. Let E/F be a field extension. We say that E is an *algebraic closure* of F if E/F is algebraic and E is algebraically closed. Algebraic closures of F are denoted by F^{alg} or \bar{F} .

Example 1.3.9. (1) \mathbb{C} is an algebraic closure of \mathbb{R} .
 (2) The algebraic closure \mathbb{Q}^{alg} of \mathbb{Q} in \mathbb{C} is an algebraic closure of \mathbb{Q} .

Algebraic closures exist in general and are unique in the following sense.

Theorem 1.3.10. *Let F be a field.*

- (1) *There exists an algebraic closure F^{alg}/F .*
- (2) *For field extensions E/F and K/F with E/F algebraic and K algebraically closed, there exists an F -embedding $E \hookrightarrow K$, which is an F -isomorphism if both E and K are algebraic closures of F .*

We postpone the proof to the next section.

Given a field extension E/F , we let $\text{Aut}_F(E)$ denote the group of F -automorphisms of E . The group law is given by composition. For any field F with algebraic closure F^{alg} , $\text{Aut}_F(F^{\text{alg}})$ is called the *absolute Galois group* of F . This group, equipped with a topology that we will specify later, governs all algebraic extensions of F at least for F of characteristic 0.

1.4 Splitting fields and normal extensions

Definition 1.4.1. Let E/F be a field extension and \mathcal{P} a family of polynomials in $F[X]$ of degree ≥ 1 . We say that \mathcal{P} *splits* in $E[X]$ if every $P \in \mathcal{P}$ splits into linear factors in $E[X]$. We say that E is a *splitting field* of \mathcal{P} over F if moreover the roots of $P \in \mathcal{P}$ generate E/F .

A splitting field of \mathcal{P} over F is an algebraic extension of F . A splitting field of $F[X] \setminus F$ is precisely an algebraic closure of F by the following lemma, which extends (1) \Leftrightarrow (3) of Remark 1.3.6.

Lemma 1.4.2. *Let E/F be an algebraic field extension. Assume that every polynomial $P(X) \in F[X]$ of degree ≥ 1 splits into linear factors in $E[X]$. Then E is algebraically closed.*

Proof. Let K/E be an algebraic extension. Then K/F is an algebraic extension by Proposition 1.3.4 (1). Let $\alpha \in K$. Since the minimal polynomial of α over F splits into linear factors in $E[X]$, we have $\alpha \in E$. Thus $K = E$. \square

We will prove the following generalization of Theorem 1.3.10. To see that Theorem 1.4.3 (2) implies Theorem 1.3.10 (2), note that in the latter we may replace E by an algebraic closure of E .

Theorem 1.4.3. *Let F be a field and \mathcal{P} a family of polynomials in $F[X]$ of degree ≥ 1 .*

- (1) *There exists a splitting field of \mathcal{P} over F .*

- (2) For field extensions E/F and K/F such that E is a splitting field of \mathcal{P} over F and \mathcal{P} splits in $K[X]$, there exists an F -embedding $E \hookrightarrow K$, which is an F -isomorphism if K is also a splitting field of \mathcal{P} over F .

We start by constructing a splitting field in the case where \mathcal{P} consist of one single polynomial.

Lemma 1.4.4. *Let F be a field and $P(X) \in F[X]$ a polynomial of degree $n \geq 1$. Then there exists a splitting field E of $P(X)$ over F such that $[E : F] \leq n!$.*

Proof. We proceed by induction on n . The case $n = 1$ is trivial. For $n \geq 2$, there exists an extension $F(\alpha)/F$ of degree $\leq n$ such that $P(\alpha) = 0$, and we apply induction hypothesis to $P(X)/(X - \alpha) \in F(\alpha)[X]$. \square

Lemma 1.4.5. *Let $(E_i/F)_{i \in I}$ be a family of field extensions. Then there exists a field extension K/F equipped with F -embeddings $E_i \hookrightarrow K$.*

Proof. Consider the commutative ring $R = \bigotimes_{i \in I} E_i$, where the tensor product is taken over F . Since R is nonzero, it admits a maximal ideal \mathfrak{m} by the axiom of choice. Take $K = R/\mathfrak{m}$. \square

Proof of Theorem 1.4.3. (1) For every $P \in \mathcal{P}$, choose a splitting field F_P/F of P , which exists by Lemma 1.4.4. By Lemma 1.4.5, there exists an extension L/F and F -embeddings $\iota_P: F_P \hookrightarrow L$ for all P . We may assume that $\iota_P(F_P)$ generate L/F . Then L is a splitting field of \mathcal{P} over F .

(2) Consider the set S of pairs (L, ι) , where L is an intermediate field for E/F and $\iota: L \hookrightarrow K$. We say $(L, \iota) \leq (L', \iota')$ if $L \subseteq L'$ and ι' extends ι . This defines a partial order on S . Every chain (L_i, ι_i) has an upper bound $(\bigcup_i L_i, \iota)$, with ι given by ι_i . By Zorn's Lemma, there exists a maximal element (L, ι) . For $\alpha \in E$ satisfying $P(\alpha) = 0$ for some $P \in \mathcal{P}$, ι extends to an F -embedding $L(\alpha) \hookrightarrow K$. By the maximality of (L, ι) , we have $\alpha \in L$. Thus $E = L$. The last assertion is clear. \square

Splitting fields have the following characterizations.

Theorem 1.4.6. *Let E/F be an algebraic extension. The following conditions are equivalent:*

- (1) Every irreducible polynomial $P(X) \in F[X]$ having a root in E splits in $E[X]$.
- (2) There exists a family \mathcal{P} of polynomial in $F[X]$ of degree ≥ 1 such that E is the splitting field of \mathcal{P} over F .
- (3) For every extension K/E and every F -embedding $\iota: E \rightarrow K$, we have $\iota(E) = E$.
- (4) There exists an extension K/E with K algebraically closed such that for every F -embedding $\phi: E \rightarrow K$, we have $\iota(E) \subseteq E$.

Proof. (1) \Rightarrow (2). It suffices to take \mathcal{P} to be the set of minimal polynomials of elements of E over F .

(2) \Rightarrow (3). For every $P \in \mathcal{P}$, ι permutes the roots of P . Since E is generated by such roots over F , $\iota(E) = E$.

(3) \Rightarrow (4). We can take K to be an algebraic closure of E .

(4) \Rightarrow (1). Let $x \in E$ be a root of some $P \in \mathcal{P}$ and let y be another root of P . Consider the F -embedding $F(x) \rightarrow K$ carrying x to y . By Theorem 1.3.10, this extends to an F -embedding $\iota: E \hookrightarrow K$. By (4), $y = \iota(x) \in E$. \square

Definition 1.4.7. A field extension E/F satisfying the conditions of Theorem 1.4.6 is said to be *normal*.

Warning 1.4.8. A subextension of a normal extension is *not* normal in general. For example, let $E \subseteq \mathbb{C}$ be the splitting field of $X^3 - 2$ over \mathbb{Q} and let $F = \mathbb{Q}(\sqrt[3]{2}) \subsetneq E$. Then E/\mathbb{Q} is normal but F/\mathbb{Q} is not. We have the following criterion for the normality of a subextension.

Proposition 1.4.9. *Let K/F be a normal extension. A subextension E/F is normal if and only if for every F -automorphism σ of K , $\sigma(E) \subseteq E$.*

Proof. The “only if” part is a special case of Condition (3) of Theorem 1.4.6. For the “if” part, let K^{alg} be an algebraic closure of K and let $\iota: E \rightarrow K^{\text{alg}}$ be an F -embedding. Then ι extends to an F -embedding $\sigma: K \rightarrow K^{\text{alg}}$. Since K/F is normal, $\sigma(K) = K$ and $\iota(E) = \sigma(E) \subseteq E$. \square

Given an algebraic extension E/F , the splitting field of the minimal polynomials P_x of elements of $x \in E$ over F is called the *normal closure* of E/F . In fact, it suffices to restrict to a set of generators of E/F . In particular, the normal closure of a finite extension is finite.

Warning 1.4.10. For a tower of field extensions $K/E/F$ with both E/F and K/E normal, K/F is *not* normal in general. For example, both $\mathbb{Q}(\sqrt{2})/\mathbb{Q}$ and $\mathbb{Q}(\sqrt[4]{2})/\mathbb{Q}(\sqrt{2})$ are normal, but $\mathbb{Q}(\sqrt[4]{2})/\mathbb{Q}$ is not normal: $\mathbb{Q}(\sqrt[4]{2}) \subseteq \mathbb{R}$ but the splitting field of $X^4 - 2$ over \mathbb{Q} in \mathbb{C} contains i (one checks easily that $X^4 - 2$ is irreducible over \mathbb{Q}).

Proposition 1.4.11. (1) *Let $K/E/F$ be a tower of field extensions. Then K/F normal implies K/E normal.*

(2) *Let $K/E/F$ and $K/E'/F$ be two factorizations. Then E'/F normal implies $E \cdot E'/E$ normal.*

(3) *Let $K/E_i/F$, $i \in I$ be a family of factorizations. Then E_i/F normal for all $i \in I$ implies $\bigcap_{i \in I} E_i$ (assuming I nonempty) and $\bigvee_{i \in I} E_i/F$ normal.*

Proof. For (2), if E'/F is the splitting field of a family of polynomials \mathcal{P} , then $E \cdot E'/E$ is the splitting field of \mathcal{P} . For (1) and (3), we check Condition (4) of Theorem 1.4.6 (with \subseteq replaced by $=$). \square

1.5 Separable extensions

Definition 1.5.1. Let F be a field.

- (1) A nonzero polynomial $P \in F[X]$ is said to be *separable* if all roots of P in a splitting field of P are simple. A nonzero polynomial $P \in F[X]$ is said to be *purely inseparable* if P has only one root in a splitting field of P .
- (2) In a field extension E/F , an algebraic element α is said to be *separable* (resp. *purely inseparable*) over F if its minimal polynomial over F is separable (resp. purely inseparable).
- (3) A field extension E/F is said to be *separable* (resp. *purely inseparable*) if every element $\alpha \in E$ is separable over F .²

²French has a word for “purely inseparable” – *radiciel*.

The *derivative* of a polynomial $P = \sum_{k=0}^d a_k X^k$ is $P' = \sum_{k=1}^d k a_k X^{k-1}$.

To unify statements in all characteristics, it is convenient to adopt the following terminology: the *characteristic exponent* p of a field F is $\max\{1, \text{char}(F)\}$. The Frobenius endomorphism $F \rightarrow F$ carrying x to x^p is a field embedding:

$$(x + y)^p = \sum_{i=0}^p \binom{p}{i} x^i y^{p-i} = x^p + y^p.$$

In particular, p -th root of an element of F is unique when it exists.

Proposition 1.5.2. *Let F be a field of characteristic exponent p .*

- (1) *A nonzero polynomial $P \in F[X]$ is separable if and only if $(P, P') = (1)$.*
- (2) *A irreducible polynomial $P \in F[X]$ is separable if and only if $P' \neq 0$. In particular, if $p = 1$, every irreducible polynomial $P \in F[X]$ is separable; if $p > 1$, an irreducible polynomial $P \in F[X]$ is inseparable if and only if $P = P_1(X^k)$ for some $P_1 \in F[X]$, $k \in \mathbb{Z}_{\geq 0}$.*
- (3) *Every irreducible polynomial $P \in F[X]$ can be written uniquely as $P(X) = P_k(X^{p^k})$ with $k \in \mathbb{Z}_{\geq 0}$ and $P_k \in F[X]$ separable. This expression is unique for $p > 1$.*
- (4) *The polynomial $aX^{p^k} - b$, $a \in F^\times$, $b \in F$, $k \in \mathbb{Z}_{\geq 0}$ is purely inseparable. Conversely, every irreducible purely inseparable polynomial in $F[X]$ is of this form.*

Proof. (1) We may assume P splits in F . Let a be a root in F . Then $P(X) = (X - a)Q(X)$, so that $P'(X) = Q(X) + (X - a)Q'(X)$. Thus a is a simple root of P if and only if $P'(a) \neq 0$. Thus P is separable if and only if P and P' have no common root.

(2) If $P' = 0$, then $(P, P') \neq (1)$. Conversely, if $(P, P') \neq (1)$, then $P \mid P'$, which implies $P' = 0$ because $\deg(P') < \deg(P)$.

(3) For $p = 1$, $P_k = P$ is separable for any k . For $p > 1$, we apply the last assertion of (2) recursively to construct P_0, P_1, \dots . The process will stop because $\deg(P_i) = \deg(P)/p^i$.

(4) Clearly $aX^{p^k} - b = a(X - \sqrt[p^k]{b/a})^{p^k}$ is purely inseparable. Conversely, if $P(X) = P_k(X^{p^k})$ as in (3) is purely inseparable, then P_k must be both separable and purely inseparable, and hence of degree 1. \square

Remark 1.5.3. By (4), for a field extension E/F of characteristic exponent p , $x \in E$ is purely inseparable over F if and only if $x^{p^k} \in F$ for some $k \in \mathbb{Z}_{\geq 0}$. Let k be the smallest such number and let $a = x^{p^k}$. Then $X^{p^k} - a$ is the minimal polynomial of x and $[F(x) : F] = p^k$. It follows that if E/F is finite and purely inseparable, then $[E : F]$ is a power of p .

Example 1.5.4. The Frobenius embedding $F \rightarrow F$ gives rise to a purely inseparable extension F/F^p , where F^p denotes the image of the Frobenius embedding. For example, for $F = \mathbb{F}_p[X]$, we have $F^p = \mathbb{F}_p[X^p]$.

Next we discuss the relationship between separability and embeddings.

Lemma 1.5.5. *Let E/F be a purely inseparable extension. Then the restriction map $\text{Hom}(E, K) \rightarrow \text{Hom}(F, K)$ is an injection for every field K .*

Proof. We may assume that K and F have the same characteristic exponent p . Let $x \in E$. Then $x^{p^k} \in F$ for some k . For any $\iota: E \rightarrow K$, $\iota(x)$ is the unique p^k -th root of $\iota(x^{p^k})$. \square

Definition 1.5.6. The *separable degree* of a finite extension E/F is $[E : F]_{\text{sep}} = \text{card}(\text{Hom}_F(E, F^{\text{alg}}))$, where F^{alg} denotes an algebraic closure of F . This definition does not depend on the choice of F^{alg} .

Lemma 1.5.7. Let F be a field of characteristic exponent p , $F(x)/F$ a simple extension with x algebraic over F of minimal polynomial $P(X) = P_k(X^{p^k})$, with P_k separable. Then $[F(x) : F]_{\text{sep}} = \deg(P_k) \mid [F(x) : F]$. In particular, x is separable over F if and only if $[F(x) : F]_{\text{sep}} = [F(x) : F]$. Moreover, x is purely inseparable over $F(x^{p^k})$ and x^{p^k} is separable over F .

Proof. The first assertion follows from the fact that P has exactly $\deg(P_k)$ distinct roots in F^{alg} . For the last assertion, note that the minimal polynomial of x^{p^k} over F is P_k . \square

Lemma 1.5.8. Let $F \subseteq E \subseteq K$ be a tower of finite extensions. Then $[K : F]_{\text{sep}} = [K : E]_{\text{sep}}[E : F]_{\text{sep}}$.

Proof. The fiber of the restriction map $\text{Hom}_F(K, F^{\text{alg}}) \rightarrow \text{Hom}_F(E, F^{\text{alg}})$ at ι can be identified with $\text{Hom}_E(K, E^{\text{alg}})$, where E^{alg} is F^{alg} , regarded as an algebraic closure of E via ι . \square

Remark 1.5.9. Let $F \subseteq E \subseteq K$ be field inclusions and $\alpha \in K$ separable (resp. purely inseparable) over F . Then α is separable (resp. purely inseparable) over E . The follows from the fact that any factor of a separable (resp. purely inseparable) polynomial is separable (resp. purely inseparable).

Theorem 1.5.10. Let E/F be an algebraic extension.

- (1) The elements of E separable over F form a subfield E_{sep} , called the separable closure of F in E . Moreover, E_{sep}/F is separable and E/E_{sep} is purely inseparable.
- (2) For E/F finite, we have $[E : F]_{\text{sep}} = [E_{\text{sep}} : F]$. In particular, a finite extension E/F is separable if and only if $[E : F]_{\text{sep}} = [E : F]$; a finite extension E/F is purely inseparable if and only if $[E : F]_{\text{sep}} = 1$.

Proof. Let us start by showing

- (0) A finite extension E/F is separable if and only if $[E : F]_{\text{sep}} = [E : F]$.

Write $E = F(a_1, \dots, a_n)$ and let $F_i = F(a_1, \dots, a_i)$. Applying Lemma 1.5.7 to F_i/F_{i-1} and the tower properties of degree and separable degree, we obtain $[E : F]_{\text{sep}} \mid [E : F]$ and that if E/F is separable, then $[E : F]_{\text{sep}} = [E : F]$. Conversely, if $[E : F]_{\text{sep}} = [E : F]$, and $x \in E$, then $[F(x) : F]_{\text{sep}} = [F(x) : F]$, so that x is separable over F by Lemma 1.5.7.

(1) For the first assertion, it suffices to show that if $x, y \in E$ are separable over F , then $F(x, y)$ is separable over F . By Lemma 1.5.7,

$$[F(x, y) : F]_{\text{sep}} = [F(x, y) : F(x)]_{\text{sep}}[F(x) : F]_{\text{sep}} = [F(x, y) : F(x)][F(x) : F] = [F(x, y) : F].$$

By (0), $F(x, y)$ is separable over F . By definition, E_{sep}/F is separable. By the last assertion of Lemma 1.5.7, E/E_{sep} is purely inseparable.

(2) $[E : F]_{\text{sep}} = [E : E_{\text{sep}}]_{\text{sep}}[E_{\text{sep}} : F]_{\text{sep}} = [E_{\text{sep}} : F]$ by Lemma 1.5.5 and (0). \square

Definition 1.5.11. For a finite extension E/F , we define the *inseparable degree* by $[E : F]_{\text{insep}} = [E : E_{\text{sep}}]$.

We have $[E : F] = [E : F]_{\text{sep}}[E : F]_{\text{insep}}$.

Remark 1.5.12. For a tower $F \subseteq E \subseteq K$ of algebraic extensions, the equality of cardinals

$$\text{card}(\text{Hom}_F(K, F^{\text{alg}})) = \text{card}(\text{Hom}_F(E, F^{\text{alg}}))\text{card}(\text{Hom}_E(K, E^{\text{alg}}))$$

holds. However, the cardinals $\text{card}(\text{Hom}_F(E, F^{\text{alg}}))$ and $[E_{\text{sep}} : F]$ are different in general. For example, for $E = \mathbb{Q}(2^{1/2^\infty}) = \mathbb{Q}(\sqrt{2}, \sqrt[4]{2}, \sqrt[8]{2}, \dots)$, $[E : \mathbb{Q}] = \aleph_0$ is countable, but $\text{Hom}_{\mathbb{Q}}(E, \mathbb{Q}^{\text{alg}}) = \lim_n \text{Hom}(\mathbb{Q}(2^{1/2^n}), \mathbb{Q}^{\text{alg}})$ is the continuum.

Warning 1.5.13. By Remark 1.5.3, for an algebraic extension E/F , the purely inseparable elements of E over F form a subfield E_{insep} . However, E/E_{insep} is not separable in general. For example, if $E = \mathbb{F}_p(X, Y)$, $F = \mathbb{F}_p(X, Y^{p^2}/(Y^p + X))$, then $E_{\text{insep}} = F$ and $E_{\text{sep}} = \mathbb{F}_p(X, Y^p)$ [B2, §V.7, exerc. 2]. Nonetheless, we will see later that E/E_{insep} is separable if E/F is normal.

Proposition 1.5.14. (1) *Let $K/E/F$ be a tower of field extensions. Then K/F is separable if and only if both K/E and E/F are separable.*

(2) *Let $K/E/F$ and $K/E'/F$ be two factorizations with E'/F separable. Then $E \cdot E'/E$ is separable.*

(3) *Let $K/E_i/F$, $i \in I$ be a family of factorizations with E_i/F separable. Then $\bigvee_{i \in I} E_i/F$ is separable.*

The same holds with “separable” replaced everywhere by “purely inseparable”.

Proof. The only nontrivial part is K/E and E/F separable implies K/F separable. As in the proof of Proposition 1.3.4 (1), we may assume K/E and E/F finite. Then the assertion follows from Theorem 1.5.10. \square

Definition 1.5.15. We say that a field F is *separably closed* if every separable extension of F is trivial.

By Theorem 1.5.10, F is separably closed if and only if every algebraic extension of F is purely inseparable.

A splitting field for all separable irreducible polynomials in $F[X]$ is called a *separable closure* F^{sep} of F . Note that F^{sep}/F is separable and F^{sep} is separably closed (here we used Proposition 1.5.14 (1)).

Proposition 1.5.16. *Let F be a field. The following conditions are equivalent:*

(1) *Every algebraic extension of F is separable.*

(2) *Every purely inseparable extension of F is trivial.*

(3) *The Frobenius endomorphism $F \rightarrow F$ is an isomorphism.*

Proof. (1) \Rightarrow (2). By (1), every purely inseparable extension is separable and hence trivial.

(2) \Rightarrow (3). By (2), the extension $F \rightarrow F$ given by the Frobenius embedding is trivial.

(3) \Rightarrow (1). For E/F algebraic and $x \in E$, let $P(X) = P_k(X^{p^k})$ be the minimal polynomial of x over F , with $P_k = \sum_i a_i X^i$ separable and $k \geq 0$. By (3), there exists $b_i = a_i^{p^{-k}} \in F$. Then $P(X) = (\sum_i b_i X^i)^{p^k}$, so that $k = 0$ and $P = P_0$ by the irreducibility of P . It follows that x is separable over F . \square

Definition 1.5.17. We say that a field F is *perfect* if it satisfies the above conditions.

This notion extends to commutative rings (of characteristic $p > 0$) using Condition (3).

Example 1.5.18. (1) Any field of characteristic 0 is perfect.

(2) Any finite field is perfect. In fact, the Frobenius embedding of a finite field must be an isomorphism.

Given a field F , a splitting field for all purely inseparable irreducible polynomials in $F[X]$ is called a *perfection* F^{perf} . Note that F^{perf}/F is purely inseparable and F^{perf} is perfect. We have $F^{\text{perf}} = F^{1/p^\infty} = \bigcup_{n=0}^{\infty} F^{1/p^n}$.

1.6 The Primitive Element Theorem

Theorem 1.6.1. *Every finite separable extension E/F admits a primitive element.*

Lemma 1.6.2. *Let F be a field. Then every finite subgroup A of F^\times is cyclic. In particular, F^\times is cyclic if F is a finite field.*

Proof. By the structure theorem of finite abelian groups, $A \simeq \bigoplus_{i=1}^n \mathbb{Z}/d_i\mathbb{Z}$ with $d_1 \mid \cdots \mid d_n$. Note that $\#A = d_1 \cdots d_n$ and each $a \in A$ satisfies $a^{d_n} = 1$. However, $X^{d_n} - 1$ has at most d_n roots. Thus $d_1 = \cdots = d_{n-1} = 1$ and $A \simeq \mathbb{Z}/d_n\mathbb{Z}$ is cyclic. \square

Proof of Theorem 1.6.1. If F is a finite field, then E is also finite. In this case, any generator of E^\times is a primitive element for E/F .

Assume F infinite. We have $E = F(x_1, \dots, x_n)$. By induction it suffices to show that $F(x_1, x_2) = F(a)$ for some a . We will show that $F(x_1, x_2) = F(x_1 + tx_2)$ for all but finitely many $t \in F$. Let P_i be the minimal polynomial of x_i . Let $R \in F(x_1 + tx_2)[X]$ be the monic greatest common divisor of $P_1(x_1 + tx_2 - tX)$ and $P_2(X)$. Then x_2 is a root of R . For every root $z \neq x_2$ of R in an algebraic closure F^{alg} of F , $y = x_1 + tx_2 - tz$ is a root of P_1 . Let T be the finite set of $t \in F$ such that $y = x_1 + tx_2 - tz$ for some root $z \in F^{\text{alg}}$ of P_2 different from x_2 and some root $y \in F^{\text{alg}}$ of P_1 . Let $t \in F \setminus T$. Then x_2 is the only root of R in F^{alg} . Since $R \mid P_2$ is separable, we have $R = X - x_2$. Thus $x_2 \in F(x_1 + tx_2)$ and $x_1 = (x_1 + tx_2) - tx_2 \in F(x_1 + tx_2)$. \square

Example 1.6.3. Let $F = \mathbb{F}_p(X, Y)$. Then F/F^p is a finite purely inseparable extension with no primitive element. Indeed, $[F : F^p] = p^2$, but $[F^p(x) : F^p] = p$ for every $x \in F \setminus F^p$.

1.7 Finite Galois extensions

Definition 1.7.1. A separable and normal field extension E/F is called a *Galois extension*. $\text{Gal}(E/F) = \text{Aut}_F(E)$ is called the *Galois group* of the extension.

Given a separable extension E/F , the normal closure is a Galois extension over F and is called the *Galois closure* of E/F .

Combining Propositions 1.4.11 and 1.5.14, we get the following properties.

- Proposition 1.7.2.** (1) Let $K/E/F$ be a tower of field extensions. Then K/F Galois implies K/E Galois.
 (2) Let $K/E/F$ and $K/E'/F$ be two factorizations. Then E'/F Galois implies $E \cdot E'/E$ Galois.
 (3) Let $K/E_i/F$, $i \in I$ be a family of factorizations. Then E_i/F Galois for all $i \in I$ implies $\bigcap_{i \in I} E_i$ (assuming I nonempty) and $\bigvee_{i \in I} E_i/F$ Galois.

In the rest of this section, we study finite Galois extensions.

Proposition 1.7.3. A finite extension E/F is Galois if and only if $[E : F] = \#\text{Aut}_F(E)$.

Proof. Let E^{alg} be an algebraic closure of E . Then $\#\text{Aut}_F(E) \leq \text{Hom}_F(E, E^{\text{alg}}) = [E : F]_{\text{sep}} \leq [E : F]$. The first inequality is an equality if and only if E/F is normal. The second inequality is an equality if and only if E/F is separable. \square

For a subgroup $H < \text{Aut}(E)$, the fixed point set

$$E^H = \{x \in E \mid \sigma(x) = x \text{ for all } \sigma \in H\}$$

is a field, called the *fixed field*.

Theorem 1.7.4 (Fixed Field Theorem). Let $H < \text{Aut}(E)$ be a finite subgroup. Then E/E^H is a Galois extension with Galois group H .

Proof. Let $x \in E$ and let $O = Hx \subseteq E$. Then x is a root of $P(X) = \prod_{y \in O} (X - y) \in E^H[X]$. Note that $P(X)$ is a separable polynomial of degree $|H|$ and $P(X)$ splits in $E[X]$. Thus E/E^H is a Galois extension. Clearly $H < \text{Gal}(E/E^H)$. Moreover, $\#\text{Gal}(E/E^H) = [E : E^H] \leq |H|$ by the following lemma. \square

Lemma 1.7.5. Let E/F be an separable extension. Then

$$\sup_{x \in E} [F(x) : F] = \begin{cases} [E : F] & E/F \text{ finite} \\ \infty & \text{otherwise.} \end{cases}$$

Proof. The finite case follows immediately from the Primitive Element Theorem. Assume that E/F is infinite. Then, for any $x \in E$, there exist $y \in E \setminus F(x)$ and $z \in E$ such that $F(x, y) = F(z) \supsetneq F(x)$ by the Primitive Element Theorem. Thus $[F(z) : F] > [F(x) : F]$. \square

We have seen $\#\text{Aut}_F(E) \leq [E : F]$ in the proof of Proposition 1.7.3. In fact, we have the following stronger result.

Corollary 1.7.6. *Let E/F be a finite extension. Then $\#\text{Aut}_F(E) \mid [E : F]$.*

Proof. Let $H = \text{Aut}_F(E)$. Then $F \subseteq E^H$, so that $\#H = [E : E^H] \mid [E : F]$. \square

Theorem 1.7.7 (finite Galois correspondence). *Let K/F be a finite Galois extension with Galois group G . Then we have a bijection*

$$\begin{aligned} \{\text{intermediate fields } E \text{ of } K/F\} &\leftrightarrow \{\text{subgroups } H < G\} \\ E &\mapsto \text{Gal}(K/E) \\ K^H &\leftarrow H \end{aligned}$$

satisfying the following properties:

- (1) (order-reversal) *For $E \leftrightarrow H$ and $E' \leftrightarrow H'$, $E \subseteq E'$ if and only if $H \supseteq H'$. In particular, $E \cap E' \leftrightarrow \langle HH' \rangle$ and $EE' \leftrightarrow H \cap H'$.*
- (2) (G -equivariance) *For $E \leftrightarrow H$ and $\sigma \in G$, $\sigma E \leftrightarrow \sigma H \sigma^{-1}$. In particular, E/F is normal if and only if H is a normal subgroup of G .*

Proof. By the Fixed Field Theorem, $H = \text{Gal}(K/K^H)$. Clearly $E \subseteq K^{\text{Gal}(K/E)}$. Moreover $[K : E] = \#\text{Gal}(K/E) = [K : K^{\text{Gal}(K/E)}]$ by the Fixed Field Theorem. Thus $E = K^{\text{Gal}(K/E)}$. Properties (1) and (2) are clear. \square

Remark 1.7.8. For $E \leftrightarrow H$ under the above bijection, we have a bijection

$$\begin{aligned} \phi: G/H &\xrightarrow{\sim} \text{Hom}_F(E, K) \\ \sigma H &\mapsto \sigma|_E, \end{aligned}$$

which is an isomorphism of groups $G/H \xrightarrow{\sim} \text{Gal}(E/F)$ for E/F normal. Indeed, ϕ is a surjection by Theorem 1.4.3. Moreover, ϕ is an injection, because for $\sigma, \sigma' \in G$, $\sigma|_E = \sigma'|_E$ if and only if $\sigma^{-1}\sigma'|_E = \text{id}_E$.

Proposition 1.7.9. *Let E and K be intermediate fields of an extension L/F . Assume that K/F is finite Galois. Then we have an isomorphism of groups*

$$\begin{aligned} \text{Gal}(EK/E) &\xrightarrow{\sim} \text{Gal}(K/E \cap K) \\ \sigma &\mapsto \sigma|_K. \end{aligned}$$

Proof. The homomorphism is clearly injective. Let H be its image. Then $K^H \subseteq (EK)^{\text{Gal}(EK/E)} = E$. Thus $K^H = E \cap K$. It follows that $H = \text{Gal}(K/E \cap K)$. \square

We say that an extension E/F is *abelian* if it is Galois and $\text{Gal}(E/F)$ is abelian.

Corollary 1.7.10. *Let E/F and K/F be finite Galois subextensions of an extension L/F . We have an injective homomorphism of groups*

$$\begin{aligned} \text{Gal}(EK/F) &\rightarrow \text{Gal}(E/F) \times \text{Gal}(K/F) \\ \sigma &\mapsto (\sigma|_E, \sigma|_K), \end{aligned}$$

which is an isomorphism if $F = E \cap K$. In particular, if E/F and K/F are both abelian, then EK/F is abelian.

Proof. The homomorphism is clearly injective. If $F = E \cap K$, then the source and target have the same cardinality: $[EK : F] = [EK : E][E : F] = [K : F][E : F]$ by Proposition 1.7.9. \square

Example 1.7.11. Let $K = \mathbb{Q}(\sqrt[3]{2}, \omega)$ be the fraction field of the irreducible polynomial $X^3 - 2$ over \mathbb{Q} , where $\omega = e^{2\pi i/3}$. Let $\alpha_n = \sqrt[3]{2}\omega^{n-1}$, $n = 0, 1, 2$ be the roots of $X^3 - 2$. Then $G = \text{Gal}(K/\mathbb{Q})$ acts faithfully on $S = \{\alpha_1, \alpha_2, \alpha_3\}$, so that we have a group embedding $G \rightarrow \Sigma_S \simeq \Sigma_3$ into the symmetric group. We have seen $[K : \mathbb{Q}] = [K : \mathbb{Q}(\sqrt[3]{2})][\mathbb{Q}(\sqrt[3]{2}) : \mathbb{Q}] = 6 = \#\Sigma_3$. Thus the embedding is an isomorphism $G \xrightarrow{\sim} \Sigma_3$. The subgroups of Σ_3 are

$$1, \langle(23)\rangle, \langle(13)\rangle, \langle(12)\rangle, \langle(123)\rangle = A_3.$$

The corresponding intermediate fields are

$$K, \mathbb{Q}(\alpha_1), \mathbb{Q}(\alpha_2), \mathbb{Q}(\alpha_3), \mathbb{Q}(\omega), \mathbb{Q}.$$

Proposition 1.7.12. Let F_0 be a field and let $K = F_0(X_1, \dots, X_n)$ be the field of rational functions, equipped with the obvious action of Σ_n . Then $K^{\Sigma_n} = F := F_0(T_1, \dots, T_n)$ is the field of rational functions in the elementary symmetric polynomials $T_k = \sum_{1 \leq i_1 < \dots < i_k \leq n} X^{i_1} \dots X^{i_k}$. Moreover, K/F is a finite Galois extension with Galois group Σ_n .

Proof. By the Fundamental Theorem of Symmetric Polynomials, $F_0[X_1, \dots, X_n]^{\Sigma_n} = F_0[T_1, \dots, T_n] = R$ is a polynomial ring in the T_k 's. Clearly $F \subseteq K^{\Sigma_n}$. Conversely, for $f = P/Q \in K^{\Sigma_n}$, where $P, Q \in F_0[X_1, \dots, X_n]$, $f = A/B$, where $B = \prod_{\sigma \in \Sigma_n} \sigma Q \in R$ and $A = fB \in R$. The last assertion follows from the fact that the action of Σ_n on K is faithful. \square

Remark 1.7.13. Given any field F and any finite group G , there exists a finitely generated extension E/F , a finite Galois extension K/E and an isomorphism $G \simeq \text{Gal}(K/E)$. Indeed, it suffices to embed G into Σ_n for some n and take $K = F(X_1, \dots, X_n)$, $E = K^G$.

1.8 Irreducibility of polynomials

Proposition 1.8.1. Let R be a Unique Factorization Domain (UFD) and let $F = \text{Frac}(R)$. Every polynomial $P(X)$ irreducible in $R[X]$ is also irreducible in $F[X]$.

Definition 1.8.2. Let F be a field. A *valuation* (of rank 1) on F is a group homomorphism $v: F^\times \rightarrow (\mathbb{R}, +)$ satisfying $v(x + y) \geq \min\{v(x), v(y)\}$ for all $x, y \in F$. We adopt the convention $v(0) = +\infty$.

Remark 1.8.3. (1) For any real number $a > 1$, we then obtain an *absolute value* $|x| = a^{-v(x)}$ that satisfies the *strong triangle inequality* $|x + y| \leq \max\{|x|, |y|\}$.
 (2) For any root of unity $\zeta \in F$, $v(\zeta) = 0$.
 (3) If $v(x) \neq v(y)$, then $v(x + y) = \min\{v(x), v(y)\}$. Indeed, if $v(x) < v(y)$, then $v(x) = v((x + y) + (-y)) \geq \min\{v(x + y), v(y)\}$ implies $v(x + y) = v(x)$.

Example 1.8.4. Let R be a UFD and $F = \text{Frac}(R)$. Let p be an irreducible element of R . Then $v_p: F^\times \rightarrow \mathbb{Z}$ carrying $u \prod q^{a_q}$ to a_p is a valuation on F , called the *p-adic valuation*. Here $u \in R^\times$, q running through associate classes of irreducible elements of R . For $R = \mathbb{Z}$, the v_p 's are the only valuations of F (Ostrowski's Theorem).

Lemma 1.8.5. *Let v be a valuation on a field F . For a polynomial $P(X) = \sum_{i=0}^n a_i X^i$, define $v(P) = \min_i v(a_i)$. Then $v(PQ) = v(P) + v(Q)$.*

In fact, v extends to a valuation of $F(X)$.

Proof. Clearly $v(PQ) \geq v(P) + v(Q)$. Let $Q = \sum_{j=0}^m b_j X^j$, $PQ = \sum_{k=0}^{n+m} c_k X^k$. Let i be the least integer such that $v(P) = v(a_i)$ and let j be the least integer such that $v(Q) = v(b_j)$. Then $c_{i+j} = \sum_k a_k b_{i+j-k}$ with $v(a_i b_j) = v(P) + v(Q)$ and $v(a_k b_{i+j-k}) > v(P) + v(Q)$ for all $k \neq i$ by Remark 1.8.3 (2). Thus $v(c_{i+j}) = v(P) + v(Q)$. \square

Proof of Proposition 1.8.1. Let $P \in R[X]$. Assume that $P = P_1 P_2$ in $F[X]$ is reducible. For every irreducible element p of R , $v_p(P_1) + v_p(P_2) = v_p(P) \geq 0$. Thus there exists an integer a_p such that $p^{a_p} P_1, p^{-a_p} P_2 \in R[X]$. It follows that there exists $c \in F^\times$ such that $P = (cP_1)(c^{-1}P_2)$ is reducible in $R[X]$. \square

Example 1.8.6. $P(X) = X^3 + X + 1$ is irreducible over \mathbb{Q} . (By the proposition, otherwise P has a factor of the form $X \pm 1$, which is not the case.)

Newton polygons

Let F be a field equipped with a valuation $v: F^\times \rightarrow \mathbb{R}$.

Definition 1.8.7. Let $P(X) = \sum_{i=0}^n a_i X^i \in F[X]$ be a nonzero polynomial. The *Newton polygon* NP_P of P is the lower convex hull of the points $\{(i, v(a_i)) \mid a_i \neq 0\}$ in \mathbb{R}^2 .

The polygon NP_P is the graph of a lower-convex piecewise-linear function defined on a closed interval of \mathbb{R} . The endpoints and breakpoints are of the form $(i, v(a_i))$. The length of the interval on which the function has slope $\lambda \in R$ is called the multiplicity of λ .

Given two nonvertical line segments $L = \overline{AB}$ and $L' = \overline{A'B'}$ (possibly of zero length) of the same slope in \mathbb{R}^2 , with A lying to the left of B and A' lying to the left of B' , we let $L + L'$ denote the line segment $\overline{A''B''}$, where $A'' = A + A'$ and $B'' = B + B'$. Given $\Gamma = \bigcup_\lambda L_\lambda$ and $\Gamma' = \bigcup_\lambda L'_\lambda$ graphs of lower-convex piecewise-linear functions defined on closed intervals of \mathbb{R} , we define $\Gamma + \Gamma' = \bigcup_\lambda (L_\lambda + L'_\lambda)$, where L_λ (resp. L'_λ) is a line segment of slope λ , the intersection of a line of slope λ with NP_P (resp. NP_Q). It is easy to see that $\Gamma + \Gamma'$ is the lower convex hull of $\{C + C' \mid C \in \Gamma, C' \in \Gamma'\}$.

Proposition 1.8.8. *Let $P, Q \in F[X]$ be nonzero. Then $NP_{PQ} = NP_P + NP_Q$.*

Proof. Let $P(X) = \sum_i a_i X^i$, $Q(X) = \sum_i b_i X^i$, $PQ(X) = \sum_i c_i X^i$. Fix a slope λ . The line segments of slope λ of NP_P and NP_Q have the form $L = \overline{(i, v(a_i))(j, v(a_j))}$, $i \leq j$ and $L' = \overline{(i', v(b_{i'}))(j', v(b_{j'}))}$, $i' \leq j'$, respectively. Then $v(a_k) \geq v(a_i) + \lambda(k-i)$ and strict inequality holds for $k \notin [i, j]$. Similarly for $v(b_k)$. Note that $c_k = \sum_l a_l b_{k-l}$.

Thus $v(c_k) \geq v(a_i) + v(b_{i'}) + \lambda(k - i - i')$ and strict inequality holds for $k \notin [i, j]$. Moreover, $v(c_{i+i'}) = v(a_i) + v(b_{i'})$ and $v(c_{j+j'}) = v(a_j) + v(b_{j'})$. Thus the line segment of NP_{PQ} of slope λ is $L + L'$. \square

Remark 1.8.9. One can show that the slopes of NP_P with multiplicities are precisely $w(\alpha)$, α running through roots of P , where w is an extension of v to a splitting field of P (such an extension always exists).

Corollary 1.8.10. *Let $P(X) = \sum_{i=0}^n a_i X^i \in F[X]$ be a polynomial with $a_0 a_n \neq 0$. Assume that there exists a valuation v on F such that NP_P is a line segment and $\frac{v(a_0) - v(a_n)}{n} \notin v(F^\times)$ for all prime divisors p of n . Then $P(X)$ is irreducible.*

Proof. Assume that $P = QR$ is reducible with $i = \deg(Q)$ satisfying $1 \leq i \leq n - 1$. Then NP_Q is a line segment of slope $\lambda = \frac{v(a_0) - v(a_n)}{n}$ so that $i\lambda \in v(F^\times)$. This contradicts with the assumption by choosing a prime divisor of n not dividing i . \square

Corollary 1.8.11. *Let $P(X) = \sum_{i=0}^n a_i X^i \in F[X]$. Assume that there exists a valuation $v: F^\times \rightarrow \mathbb{Z}$ such that $v(a_0) = 1$, $v(a_n) = 0$, and $v(a_i) \geq 1$ for all $i = 1, \dots, n - 1$. Then $P(X)$ is irreducible.*

Such a polynomial is called an *Eisenstein polynomial* for v .

Example 1.8.12. (1) $X^4 + 2X + 2 \in \mathbb{Q}[X]$ is an Eisenstein polynomial for v_2 and hence is irreducible.
 (2) $X^5 + 4X + 4 \in \mathbb{Q}[X]$ is irreducible by Corollary 1.8.10 applied to v_2 .

1.9 Galois groups of polynomials

Let F be a field and $P(X) \in F[X]$ a separable polynomial. Let K be the splitting field of P over F , which is a finite Galois extension of F . Every finite Galois extension of F can be obtained in this way. The Galois group $G = \text{Gal}(K/F)$ is also called the Galois group of P over F . Note that G acts faithfully on the set S of roots of P in K : we have a group embedding $G \rightarrow \Sigma_S$.

Lemma 1.9.1. *The is a bijection between irreducible factors of $P(X)$ in $F[X]$ and orbits O of S under G . More precisely, we have $P(X) = c \prod_O Q_O(X)$, where $c \in F^\times$ and $Q_O(X) = \prod_{\alpha \in O} (X - \alpha) \in F[X]$ is irreducible. In particular, $P(X) \in F[X]$ is irreducible if and only if G acts transitively on S . Moreover, if $P(X) \in F[X]$ is irreducible, then $\#S \mid \#G$.*

Proof. Clearly $Q_O(X) \in K[X]^G = F[X]$. Moreover, any factorization of Q_O corresponds to a partition of O into G -stable subsets. Thus Q_O is irreducible. For the last assertion, note that $[F(\alpha) : F] = \#S$ for any $\alpha \in S$ (or equivalently $\#(G/H) = \#S$, where $H < G$ is the subgroup fixing α). \square

We fix an enumeration $\alpha_1, \dots, \alpha_n$ of S , which induces $\Sigma_S \simeq \Sigma_n$. Let $\Delta(P) = \prod_{i < j} (\alpha_i - \alpha_j) \in K$. For $\sigma \in G$, $\sigma(\Delta(P)) = \text{sgn}(\sigma)\Delta(P)$, where $\text{sgn}(\sigma) = \pm 1$ denotes the signature of σ . Thus $D(P) = \Delta(P)^2 \in K^G = F$, which does not depend on the enumeration of S and is called the *discriminant* of P . (Note that $D(P)$ can be defined without assuming P separable and $D(P) \neq 0$ if and only if P is separable.)

Example 1.9.2. (1) $D(X^2 + bX + c) = (\alpha_1 - \alpha_2)^2 = b^2 - 4c$.

(2) $D(X^3 + bX^2 + cX + d) = -4b^3d + b^2c^2 + 18bcd - 4c^3 - 27d^2$. In particular, $D(X^3 + cX + d) = -4c^3 - 27d^2$.

For $\text{char}(F) = 2$, $\Delta(P) \in F$. In this case, let $\delta(P) = \sum_{i < j} \alpha_i / (\alpha_i + \alpha_j)$. For $\sigma \in G$,

$$\sigma(\delta(P)) = \delta(P) + \begin{cases} 0 & \sigma \in A_n \\ 1 & \text{otherwise.} \end{cases}$$

Thus $d(P) = \delta(P)^2 + \delta(P) \in K^G = F$, which does not depend on the enumeration of S .

Proposition 1.9.3.

- (1) Assume $\text{char}(F) \neq 2$. Then $\text{Gal}(K/F(\Delta(P))) = G \cap A_n$. In particular, $G < A_n$ if and only if $D(P) \in F^{\times 2}$.
- (2) Assume $\text{char}(F) = 2$. Then $\text{Gal}(K/F(\delta(P))) = G \cap A_n$. In particular, $G < A_n$ if and only if $X^2 + X + d(P)$ has a root in F .

Proof. For (1), $\sigma(\Delta(P)) = \Delta(P)$ if and only if $\sigma \in A_n$. It follows that $F(\Delta(P)) = F$ if and only if $G < A_n$. (2) is similar, with $\Delta(P)$ replaced by $\delta(P)$. \square

Remark 1.9.4. Assume $\deg(P) = 2$. If P splits, then $G = 1$. If P is irreducible, then $P = \Sigma_2$.

Remark 1.9.5. Assume $\deg(P) = 3$. If P splits, then $G = 1$. If $P = Q(X - \alpha_3)$ with $Q \in F[X]$ irreducible and $\alpha_3 \in F$, then $G = \Sigma_2$. If P is irreducible, then $G = A_3$ or $G = \Sigma_3$, which can be determined by Proposition 1.9.3.

Example 1.9.6. $P(X) = X^3 - 3X - 1 \in \mathbb{Q}[X]$. Since $P(X)$ is irreducible and $D(P) = -4(-3)^3 - 27 = 81 = 9^2$, the Galois group is A_3 .

Quartic equations

Assume $\deg(P) = 4$. We have the following possibilities:

- (1) $P = Q(X - \alpha_4)$ in $F[X]$. Then $G < \Sigma_3$ is as in Remark 1.9.5.
- (2) $P = QR$ with Q and R irreducible of degree 2 in $F[X]$. Then we number the roots so that $Q = (X - \alpha_1)(X - \alpha_2)$ and $R = (X - \alpha_3)(X - \alpha_4)$. Then $G = \{\text{id}, (12)(34)\} < A_4$ or $G = \langle (12), (34) \rangle \not< A_4$. This can be determined for example by Proposition 1.9.3.
- (3) P irreducible. There are five possibilities for G up to conjugation:
- Σ_4
 - A_4
 - $C_4 = \langle (1234) \rangle$
 - $D_4 = \langle (1234), (13) \rangle$ (dihedral group)
 - $V = \{\text{id}, (12)(34), (13)(24), (14)(23)\}$.

We have $V < A_4$, $C_4 \not< A_4$, $D_4 \not< A_4$. Proposition 1.9.3 is not enough to determine G .

Example 1.9.7. (1) For $P(X) = (X^2 - 2)(X^2 - 8)$, $G = \{\text{id}, (12)(34)\}$.

(2) For $P(X) = (X^2 + 1)(X^2 - 2)$, $G = \langle (12), (34) \rangle$.

Consider the set of partitions

$$T = \{\{\{1, 2\}, \{3, 4\}\}, \{\{1, 3\}, \{2, 4\}\}, \{\{1, 4\}, \{2, 3\}\}\}$$

of $\{1, 2, 3, 4\}$, equipped with the obvious action of Σ_4 . The homomorphism $\Sigma_4 \rightarrow \Sigma_T$ is surjective of kernel V . Corresponding the elements of K

$$\alpha = \alpha_1\alpha_2 + \alpha_3\alpha_4, \quad \beta = \alpha_1\alpha_3 + \alpha_2\alpha_4, \quad \gamma = \alpha_1\alpha_4 + \alpha_2\alpha_3.$$

They are distinct: $\alpha - \beta = (\alpha_1 - \alpha_4)(\alpha_2 - \alpha_3)$ and similarly for $\alpha - \gamma$ and $\beta - \gamma$. We thus have an obvious bijection between T and $\{\alpha, \beta, \gamma\}$, equivariant under G . The polynomial

$$Q(X) = (X - \alpha)(X - \beta)(X - \gamma) \in F[X]$$

is called the cubic resolvent of $P(X)$. (An easy computation shows $D(P) = D(Q)$ and, if $\text{char}(F) \neq 2$, $d(P) = d(Q)$.) We have proved the following.

Proposition 1.9.8. $K^{G \cap V} = F(\alpha, \beta, \gamma)$ is the splitting field of $Q(X)$.

Corollary 1.9.9. Assume that $P \in F[X]$ is irreducible of degree 4 and let $E = F(\alpha, \beta, \gamma)$. Then

- (1) If $[E : F] = 1$, then $G = V$;
- (2) If $[E : F] = 2$, then G is conjugate to C_4 or D_4 ; moreover, in this case, G is conjugate to D_4 if and only if $P(X)$ remains irreducible in $E[X]$;
- (3) If $[E : F] = 3$, then $G = A_4$;
- (4) If $[E : F] = 6$, then $G = \Sigma_4$.

Proof. Let us compute $\text{Gal}(E/F) \simeq G/G \cap V$ for each possibility of G . We have $V/V = 1$, $C_4/C_4 \cap V \simeq \{\text{id}, (\alpha\gamma)\} \simeq D_4/D_4 \cap V$, $A_4/A_4 \cap V \simeq A_T$, $\Sigma_4/\Sigma_4 \cap V \simeq \Sigma_T$.

Moreover, $\text{Gal}(K/E) = G \cap V$. For the last assertion of (2), note that $C_4 \cap V = \{\text{id}, (13)(24)\}$ does not act transitively on $\{1, 2, 3, 4\}$, while $D_4 \cap V = V$ acts transitively on $\{1, 2, 3, 4\}$. \square

For $P(X) = X^4 + bX^3 + cX^2 + dX + e$, its cubic resolvent is $Q(X) = X^3 - cX^2 + (bd - 4e)X - (b^2e - 4ce + d^2)$. In particular, for $b = 0$, $Q(X) = X^3 - cX^2 - 4eX + (4ce - d^2)$.

Example 1.9.10. $P(X) = X^4 + 4X^2 + 2 \in \mathbb{Q}[X]$. This is an Eisenstein polynomial for 2 and hence irreducible. Its cubic resolvent is $Q(X) = X^3 - 4X^2 - 8X + 32 = (X - 4)(X^2 - 8)$. Over $E = \mathbb{Q}(\sqrt{2})$, $P(X) = (X^2 + 2 - \sqrt{2})(X^2 + 2 + \sqrt{2})$. Thus $G \simeq C_4$.

Example 1.9.11. $P(X) = X^4 - 2X + 2 \in \mathbb{Q}[X]$. This is an Eisenstein polynomial for 2 and hence irreducible. Its cubic resolvent is $Q(X) = X^3 - 8X - 4$, which is irreducible in $\mathbb{Q}[X]$ by Corollary 1.8.10. We have $D(Q) = -4(-8)^3 - 27(-4)^2 = 1616$, which is not a square in \mathbb{Q} . Thus, $[E : \mathbb{Q}] = 6$ and $G = \Sigma_4$.

For a given finite group G , the inverse Galois problem asks whether there exists a finite Galois extension K/\mathbb{Q} with an isomorphism $G \simeq \text{Gal}(K/\mathbb{Q})$. This is true for many finite groups, but remains an open problem in general.

1.10 Finite fields

Every finite field F has characteristic $p > 1$. Moreover, F is a finite extension of \mathbb{F}_p , so that $\#F = p^{[F:\mathbb{F}_p]}$.

Theorem 1.10.1. *Let $d \geq 1$ and $q = p^n$. There exists a finite field F with $\#F = q$, unique up to isomorphism, denoted by \mathbb{F}_q . It is a splitting field of the separable polynomial $X^q - X$ over \mathbb{F}_p .*

Note that in a field F with $\#F = q$, $x^q = x$ for all $x \in F$. Indeed, for $x \in F^\times$, $x^{q-1} = 1$.

Proof. Let \mathbb{F}_q be a splitting field of $P(X) = X^q - X$ over \mathbb{F}_p . Since $P' = -1$ and $(P, P') = (1)$, P is separable and has exactly q roots. Let S be the set of roots of P in \mathbb{F}_q . Then S contains \mathbb{F}_p and is stable under addition, multiplication, and taking inverses (of nonzero elements). Thus $\mathbb{F}_q = S$ and $\#\mathbb{F}_q = q$.

Let F be a field with $\#F = q$. Then, since $x^q = x$ for all $x \in F$, there exists an embedding $F \hookrightarrow \mathbb{F}_q$, which must be an isomorphism. \square

Corollary 1.10.2. *Let E/F and K/F be extensions of finite fields with $\#F = q$, $\#E = q^m$, $\#K = q^n$. Then there exists an F -embedding $E \rightarrow K$ if and only if $m \mid n$.*

Proof. If such an F -embedding exists, then, by the tower property of degrees, we have $n = m[K : E]$. Conversely, assume $m \mid n$. Note that K is the splitting field of $P(X) = X^{q^n} - X$ over F . Moreover, every element $x \in E$ satisfies $x^{q^m} = x$ and hence is a root of P . Thus there exists an F -embedding $E \rightarrow K$. \square

Theorem 1.10.3. *Let K/F be an extension of finite fields with $\#F = q$. Then K/F is a Galois extension and $\text{Gal}(K/F)$ is a cyclic group generated by $\text{Fr}_q: x \mapsto x^q$.*

Proof. We have seen that K/F is the splitting field of a separable polynomial and hence is a Galois extension. Let $n = [K : F] = \#\text{Gal}(K/F)$. Then the order d of Fr_q divides n . Every $x \in K$ satisfies $x^{q^d} = x$. Since $X^{q^d} - X$ has (at most) q^d roots, $\#K = q^n \leq q^d$. Thus $d = n$ and $\text{Gal}(K/F) = \langle \text{Fr}_q \rangle$. \square

1.11 Cyclotomic fields

Let F be a field.

Definition 1.11.1. For an integer $n \geq 1$, we say that $\zeta \in F$ is an n -th root of unity if $\zeta^n = 1$. We let $\mu_n(F) \subseteq F^\times$ denote the group of n -th roots of unity in F . We say $\zeta \in F^\times$ is a primitive n -th root of unity if it has order n .

Lemma 1.11.2. $\mu_n(F)$ is a cyclic group of order dividing n . Moreover, if $n = p^a m$ for $a, m \in \mathbb{Z}_{\geq 1}$, where p denotes the characteristic exponent of F , then $\mu_n(F) = \mu_m(F)$.

Proof. There are at most n solutions of $X^n - 1$. Thus $\mu_n(F) \subseteq F^\times$ is a finite subgroup. By Lemma 1.6.2, $\mu_n(F)$ is cyclic. Then $\#\mu_n(F)$ is the order of a generator, which must divide n . The last assertion is clear, as $x^{p^a} = 1$ if and only if $x = 1$. \square

It follows that if ζ is a primitive n -th roots of unity of F , then $\text{char}(F) \nmid n$.

Proposition 1.11.3. *Let $F(\zeta_n)/F$ be a field extension where ζ_n is a primitive n -th roots of unity. Then $F(\zeta_n)/F$ is the splitting field of the separable polynomial $P(X) = X^n - 1$ over F and we have a group embedding $G = \text{Gal}(F(\zeta_n)/F) \rightarrow (\mathbb{Z}/n\mathbb{Z})^\times$ carrying σ to $a \in (\mathbb{Z}/n\mathbb{Z})^\times$ satisfying $\sigma(\zeta_n) = \zeta_n^a$.*

$F(\zeta_n)/F$ is called the n -th cyclotomic extension of F .

Proof. Since ζ_n generates $\mu_n(F)$, $F(\zeta_n)$ is the splitting field of $P(X) = X^n - 1$. Note that $P(X)$ and $P'(X) = nX^{n-1}$ are coprime, so that P is separable. For every $\sigma \in G$, $\sigma(\zeta_n)$ is also a generator of $\mu_n(F)$, so that $\sigma(\zeta_n) = \zeta_n^a$ for some $a \in (\mathbb{Z}/n\mathbb{Z})^\times$. The injectivity of the group homomorphism is clear. \square

Let F be a field with $\text{char}(F) \nmid n$. Let $\Phi_n(X) = \prod_{\zeta} (X - \zeta)$, where ζ runs through the n -th primitive n -th roots of unity in a separable closure of F .

Lemma 1.11.4. $\Phi_n \in F[X]$ and has degree $\varphi(n)$, where $\varphi(n) = \#(\mathbb{Z}/n\mathbb{Z})^\times$ is Euler's totient function. Moreover, $X^n - 1 = \prod_{d|n} \Phi_d(X)$.

Proof. Let K be the splitting field of $X^n - 1$ over F . For every $\sigma \in \text{Gal}(K/F)$, σ permutes the primitive n -th roots of unity, which are in bijection with $(\mathbb{Z}/n\mathbb{Z})^\times$. Finally, $X^n - 1 = \prod_{\zeta \in \mu_n(K)} (X - \zeta)$. \square

We now restrict to the case $F = \mathbb{Q}$.

Theorem 1.11.5. For $F = \mathbb{Q}$, $\Phi_n(X) \in \mathbb{Z}[X]$ and is irreducible. Moreover, the group embedding in Proposition 1.11.3 is an isomorphism $\text{Gal}(\mathbb{Q}(\zeta_n)/\mathbb{Q}) \xrightarrow{\sim} (\mathbb{Z}/n\mathbb{Z})^\times$.

Lemma 1.11.6. Let R be UFD of fraction field F and let $P, Q \in F[X]$ be monic polynomial with $Q \in R[X]$ and $P \mid Q$. Then $P \in R[X]$.

Proof. Let $NP = Q$ in $F[X]$. For any irreducible element p of F , $v_p(N) + v_p(P) = v_p(Q) = 0$ and $v_p(N), v_p(P) \leq 0$. Thus $v_p(P) = 0$ for all p . \square

Proof of Theorem 1.11.5. Since $\Phi_n(X) \mid X^n - 1$ in $\mathbb{Q}[X]$, $\Phi_n(X) \in \mathbb{Z}[X]$. It suffices to show that $\Phi_n(X)$ is irreducible. Indeed, this implies $[\mathbb{Q}(\zeta_n) : \mathbb{Q}] = \deg(\Phi_n) = \#(\mathbb{Z}/n\mathbb{Z})^\times$, so that the homomorphism in Proposition 1.11.3 must be an isomorphism.

Assume that $\Phi_n = PQ$ with $P, Q \in \mathbb{Q}[X]$ monic of degree ≥ 1 . Then $P, Q \in \mathbb{Z}[X]$. Every root of Φ_n has the form ζ_n^a with $(a, n) = 1$. Thus there exists a prime number $p \nmid n$ and a root ζ of P such that ζ^p is a root of Q . Then $P(X^p)$ and $P(X)$ are not coprime in $\mathbb{Q}[X]$. It follows that there exists $R(X) \in \mathbb{Z}[X]$ dividing $P(X)$ and $Q(X^p)$. Consider the reductions $\bar{P}, \bar{Q} \in \mathbb{F}_p[X]$ of P, Q, R modulo p . Then $\bar{Q}(X^p) = \bar{Q}(X)^p$ is not prime to \bar{P} . It follows that \bar{P} and \bar{Q} are not coprime. However $\bar{P}\bar{Q} \mid X^n - 1$ and $X^n - 1$ is separable in $\mathbb{F}_p[X]$. Contradiction. \square

Example 1.11.7. For $n = p^a$, $\Phi_{p^a}(X) = (X^{p^a} - 1)/(X^{p^{a-1}} - 1) = \sum_{i=1}^p X^{p^{a-1}i}$.

Remark 1.11.8. More generally, Φ_n is given by the Möbius inversion formula

$$\Phi_n = \prod_{d|n} (X^d - 1)^{\mu(n/d)},$$

where μ is the Möbius function

$$\mu(p_1 \cdots p_m) = \begin{cases} (-1)^m & \text{if } p_1, \dots, p_m \text{ are distinct primes} \\ 0 & \text{otherwise.} \end{cases}$$

Indeed, $\prod_{d|n} (X^d - 1)^{\mu(n/d)} = \prod_{c|d|n} \Phi_c(X)^{\mu(n/d)}$, where the multiplicity of $\Phi_c(X)$ is

$$\sum_{c|d|n} \mu(n/d) = \begin{cases} 1 & c = n \\ 0 & \text{otherwise} \end{cases}$$

by the elementary identity

$$\sum_{d|n} \mu(d) = \begin{cases} 1 & n = 1 \\ 0 & n > 1. \end{cases}$$

Example 1.11.9. $\Phi_{12}(X) = (X^{12} - 1)(X^6 - 1)^{-1}(X^4 - 1)^{-1}(X^2 - 1) = \frac{X^6+1}{X^2+1} = X^4 - X^2 + 1$.

Every subfield of $\mathbb{Q}(\zeta_n)$ is an abelian extension of \mathbb{Q} . The proof of the following important theorem in number theory is beyond the scope of these lectures.

Theorem 1.11.10 (Kronecker–Weber). *Every finite abelian extension of \mathbb{Q} can be embedded into $\mathbb{Q}(\zeta_n)$ for some n .*

A finite extension of \mathbb{Q} is called a *number field*. The problem of explicit construction of abelian extensions of number fields is known as Kronecker’s *Jugendtraum* or Hilbert’s 12th problem. The theory of complex multiplication (CM) solves this CM fields, but the problem for more general number fields remains open.

1.12 Trace and norm

Let E/F be a finite field extension.

Definition 1.12.1. For $\alpha \in E$, we let $\text{tr}_{E/F}(\alpha) = \text{tr}(m_\alpha) \in F$ and $N_{E/F}(\alpha) = \det(m_\alpha) \in F$, where $m_\alpha: E \rightarrow E$ is the F -linear map defined by $m_\alpha(\beta) = \alpha\beta$.

It follows from standard facts of the trace and determinant of linear operators that $\text{tr}_{E/F}: E \rightarrow F$ is an F -linear map and

$$N_{E/F}(\alpha\beta) = N_{E/F}(\alpha)N_{E/F}(\beta), \quad N_{E/F}(a\alpha) = a^{[E:F]}(\alpha),$$

where $a \in F$. Moreover, $N_{E/F}(\alpha) = 0$ if and only if $\alpha = 0$. In particular, $N_{E/F}$ induces a homomorphism $E^\times \rightarrow F^\times$.

Example 1.12.2. Let $E = F(\alpha)$ and let $P(X) = X^n + a_{n-1}X^{n-1} + \cdots + a_0$ be the minimal polynomial of α . Then $\text{tr}_{E/F}(\alpha) = -a_{n-1}$ and $N_{E/F}(\alpha) = (-1)^n a_0$. Indeed, in the basis $\{1, \alpha, \dots, \alpha^{n-1}\}$, m_α is represented by the matrix

$$\begin{pmatrix} 0 & 0 & \cdots & 0 & -a_0 \\ 1 & 0 & \cdots & 0 & -a_1 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & 1 & -a_{n-1} \end{pmatrix}.$$

(In fact, P is the characteristic polynomial of m_α .)

Lemma 1.12.3. *We have*

$$\text{tr}_{E/F}(\alpha) = [E : F(\alpha)]\text{tr}_{F(\alpha)/F}(\alpha), \quad N_{E/F}(\alpha) = N_{F(\alpha)/F}(\alpha)^{[E:F(\alpha)]}.$$

Proof. Let $(v_i)_{1 \leq i \leq m}$ be a basis of $E/F(\alpha)$, where $m = [E : F(\alpha)]$ and let (w_j) be a basis of $F(\alpha)/F$. Let A be the matrix of α under (w_j) . Then the matrix of α under the basis $(v_i w_j)$ of E/F is $\text{diag}(A, \dots, A)$ (A repeated m times). \square

Proposition 1.12.4. *Let K/F be a normal extension containing E . Then, for any $\alpha \in E$,*

$$\text{tr}_{E/F}(\alpha) = [E : F]_{\text{insep}} \sum_{\iota} \iota(\alpha), \quad N_{E/F}(\alpha) = \prod_{\iota} \iota(\alpha)^{[E:F]_{\text{insep}}},$$

where ι runs through F -embeddings $E \rightarrow K$.

Proof. The minimal polynomial $P(X) \in F[X]$ of α satisfies

$$P(X) = \prod_{\lambda} (X - \lambda(\alpha))^{[F(\alpha):F]_{\text{insep}}},$$

where λ runs through F -embeddings $F(\alpha) \rightarrow K$. Thus for $E = F(\alpha)$, the assertion follows from Example 1.12.2. The general case follows then from Lemma 1.12.3 and the fact that each fiber of the restriction map $\text{Hom}_F(E, K) \rightarrow \text{Hom}_F(F(\alpha), K)$ has cardinality $[E : F(\alpha)]_{\text{sep}}$. \square

The following generalizes Lemma 1.12.3.

Proposition 1.12.5. *Let $K/E/F$ be finite extensions. For every $\alpha \in K$,*

$$\text{tr}_{K/F}(\alpha) = \text{tr}_{E/F}(\text{tr}_{K/E}(\alpha)), \quad N_{K/F}(\alpha) = N_{E/F}(N_{K/E}(\alpha)).$$

Proof. We prove the assertion for traces. The assertion for norms can be proved similarly. Let L/F be a normal extension containing K . We have

$$\text{tr}_{E/F}(\text{tr}_{K/E}(\alpha)) = [E : F]_{\text{insep}} \sum_{\lambda} \lambda([\text{tr}_{K/E}(\alpha)]) = [E : F]_{\text{insep}} \sum_{\lambda} \sum_{\iota} \iota(\alpha) = [E : F]_{\text{insep}} \sum_{\lambda} \tilde{\lambda}(\alpha),$$

where $\iota \in \text{Hom}_E(K, L)$, $\lambda \in \text{Hom}_F(E, L)$. For each λ , $\tilde{\lambda}: L \rightarrow L$ is a chosen extension of λ . The fiber of the restriction map $\text{Hom}_F(K, L) \rightarrow \text{Hom}_F(E, L)$ at λ is $\{\tilde{\lambda}\iota \mid \iota \in \text{Hom}_E(K, L)\}$. Thus

$$\text{tr}_{E/F}(\text{tr}_{K/E}(\alpha)) = [E : F]_{\text{insep}} \sum_{\mu \in \text{Hom}_F(K, L)} \mu(\alpha) = \text{tr}_{K/F}(\alpha).$$

\square

The above proposition holds in fact for any E -linear map $K \rightarrow K$. We refer to [李, 定理 7.8.5] for a generalization and a direct proof.

Proposition 1.12.6. (1) If E/F is separable, then $\text{tr}_{E/F}: E \rightarrow F$ is surjective.
 (2) If E/F is inseparable, then $\text{tr}_{E/F}$ is zero.

Proof. (2) follows from Proposition 1.12.4. For (1), it suffices to show that $\text{tr}_{E/F}$ is nonzero. Let α be a primitive element for E/F . Then $1, \alpha, \dots, \alpha^{n-1}$ is a basis of E/F , where $n = [E : F]$. Let K/F be a normal extension containing E and let $\sigma_1, \dots, \sigma_n: E \rightarrow K$ be the F -embeddings. The elements $\sigma_1(\alpha), \dots, \sigma_n(\alpha)$ are distinct, so that the Vandermonde matrix $A = (\sigma_j(\alpha^{i-1}))$ is invertible. It follows that $\begin{pmatrix} \text{tr}_{E/F}(1) \\ \vdots \\ \text{tr}_{E/F}(\alpha^{n-1}) \end{pmatrix} = A \begin{pmatrix} 1 \\ \vdots \\ 1 \end{pmatrix}$ is nonzero. \square

It is harder to determine the image of $N_{E/F}$.

1.13 Hilbert's Theorem 90

Let E/F be a finite Galois extension and let $G = \text{Gal}(E/F)$. For any $\beta \in E$, $\text{tr}_{E/F}(\sigma\beta - \beta) = 0$. For any $\beta \in E^\times$, $N_{E/F}(\sigma\beta/\beta) = 1$.

A finite Galois extension with cyclic Galois group is called a *cyclic extension*. For such extensions, the kernels of the trace and norm maps can be determined as follows.

Theorem 1.13.1. Let E/F be a finite cyclic extension and let $\sigma \in \text{Gal}(E/F)$ be a generator.

- (1) If $\alpha \in E$ satisfies $\text{tr}_{E/F}(\alpha) = 0$, then $\alpha = \sigma(\beta) - \beta$ for some $\beta \in E$.
- (2) (Hilbert 90) If $\alpha \in E^\times$ satisfies $N_{E/F}(\alpha) = 1$, then $\alpha = \sigma(\beta)/\beta$ for some $\beta \in E^\times$.

Hilbert's original statement [H1, §54, Satz 90] has some extra assumptions (F is a number field and $[E : F]$ is a prime number).

We will prove a more general form of Theorem 1.13.1 involving group cohomology. Let G be a group. An abelian group equipped with a G -action by automorphisms of abelian groups is called a G -module.

Definition 1.13.2. Let M be a G -module. A *crossed homomorphism* is a map $f: G \rightarrow M$ such that $f(\sigma\tau) = f(\sigma) + \sigma f(\tau)$ for all $g, h \in G$. For $m \in M$, let $d^0(m): G \rightarrow M$ be the $\sigma \mapsto \sigma m - m$, which is clearly a crossed homomorphism. Indeed, $\sigma\tau m - m = (\sigma m - m) + \sigma(\tau m - m)$. A crossed homomorphism of the form $d^0(m)$ for some $m \in M$ is called a *principal* crossed homomorphism. We let $Z^1(G, M)$ and $B^1(G, M)$ denote the abelian groups of crossed homomorphisms and principal crossed homomorphisms, respectively. We define the *first cohomology* of G with coefficients in M to be

$$H^1(G, M) = Z^1(G, M)/B^1(G, M).$$

Example 1.13.3. If the action of G on M is trivial, then $B^1(G, M) = 0$ and $H^1(G, M) = Z^1(G, M) = \text{Hom}(G, M) \simeq \text{Hom}(G_{\text{ab}}, M)$, where $G_{\text{ab}} = G/[G, G]$ denotes the abelianization of G .

Example 1.13.4. Let $G = \langle \sigma \rangle$ be a cyclic group of order n . Then we have an isomorphism $Z^1(G, M) \xrightarrow{\sim} \ker(N)$, where $N: M \rightarrow M$ is defined by $N(m) = \sum_{g \in G} gm$. The inverse carries m to $f: G \rightarrow M$ defined by $f(\sigma^i) = \sum_{j=0}^{i-1} \sigma^j m$ for $i \geq 0$. Under this bijection, the image of $B^1(G, M)$ is $\text{im}(\sigma - \text{id}) = \{\sigma m - m \mid m \in M\}$. Thus the bijection induces an isomorphism $H^1(G, M) \simeq \ker(N)/\text{im}(\sigma - \text{id})$.

For $M = E$, where E/F is a cyclic extension with group G , we have $N = \text{tr}_{E/F}$. For $M = E^\times$, we have $N = N_{E/F}$.

In view of the example, Theorem 1.13.1 follows from the cyclic case of the following theorem.

Theorem 1.13.5. *Let E/F be a finite Galois extension and let $G = \text{Gal}(E/F)$. Then $H^1(G, E) = 0$ and $H^1(G, E^\times) = 1$.*

The triviality of $H^1(G, E^\times)$ was proved by Speiser.

Lemma 1.13.6 (Dedekind–Artin). *Let Γ be a monoid and let R be a commutative domain. Then $\text{Hom}(\Gamma, (R, \times))$ is R -linearly independent. In other words, if $\chi_1, \dots, \chi_n: \Gamma \rightarrow (R, \times)$ are distinct homomorphisms and $r_1, \dots, r_n \in R$ are such that $\sum_{i=1}^n r_i \chi_i(g) = 0$ for all $g \in \Gamma$, then $r_1 = \dots = r_n = 0$.*

Note that in the lemma we may replace R by its fraction field without loss of generality.

Proof. We proceed by induction on n . For $n = 1$, it suffices to take $g = 1$. For $n \geq 2$, it suffices to show $r_n = 0$. Choose $h \in \Gamma$ such that $\chi_1(h) \neq \chi_n(h)$. Then

$$\sum_{i=2}^n r_i (\chi_i(h) - \chi_1(h)) \chi_i(g) = \sum_{i=1}^n r_i \chi_i(hg) - \chi_1(h) \sum_{i=1}^n r_i \chi_i(g) = 0.$$

By induction hypothesis, $r_n(\chi_n(h) - \chi_1(h)) = 0$, which implies that $r_n = 0$. \square

Proof of Theorem 1.13.5. Let $f: G \rightarrow E^\times$ be a crossed homomorphism. Note that this means $f(\sigma\tau) = f(\sigma)\sigma(f(\tau))$ for all $\sigma, \tau \in G$. By the lemma applied to $\Gamma = E^\times$, $\sum_{\tau \in G} f(\tau)\tau: E^\times \rightarrow E$ is not the zero map. There exists $x \in E^\times$ such that $y := \sum_{\tau \in G} f(\tau)\tau(x) \neq 0$. Then, for every $\sigma \in G$,

$$\sigma(y) = \sum_{\tau \in G} \sigma(f(\tau))\sigma\tau(x) = \sum_{\tau \in G} f(\sigma)^{-1} f(\sigma\tau)\sigma\tau(x) = f(\sigma)^{-1}y.$$

In other words, $f(\sigma) = \sigma(y^{-1})/y^{-1}$.

Let $f: G \rightarrow E$ be a crossed homomorphism. Let $x \in E$ such that $\text{tr}_{E/F}(x) \neq 0$ and let $y = \sum_{\tau \in G} f(\tau)\tau(x)$. Then, for every $\sigma \in G$,

$$\sigma(y) = \sum_{\tau \in G} \sigma(f(\tau))\sigma\tau(x) = \sum_{\tau \in G} (f(\sigma\tau) - f(\sigma))\sigma\tau(x) = y - f(\sigma)\text{tr}_{E/F}(x).$$

In other words, $f(\sigma) = \sigma(z) - z$, where $z = -y/\text{tr}_{E/F}(x)$. \square

Remark 1.13.7. The Normal Basis Theorem [李, 定理 9.5.6] states that $E \simeq F[G]$ as $F[G]$ -modules, which implies $H^n(G, E) = 0$ for all $n \geq 1$. On the other hand, $H^2(G, E^\times)$ is in general nontrivial and meaningful.

1.14 Kummer and Artin–Schreier theories

We will deduce Kummer and Artin–Schreier theories from long exact sequences for cohomology of groups.

Definition 1.14.1. We say that a sequence of groups $A \xrightarrow{f} B \xrightarrow{g} C$ is *exact at B* if $\text{im}(f) = \ker(g)$. We say that a sequence of groups $A^0 \rightarrow A^1 \rightarrow \dots \rightarrow A^n$ is *exact* if it is exact at each A^i , $1 \leq i \leq n-1$.

We restrict our attention to exact sequences of abelian groups.

Example 1.14.2. (1) A sequence $0 \rightarrow A \rightarrow 0$ is exact if and only if $A = 0$.

(2) A sequence $0 \rightarrow A \xrightarrow{f} B$ is exact if and only if f is injective.

(3) A sequence $A \xrightarrow{f} B \rightarrow 0$ is exact if and only if f is surjective.

(4) A sequence $0 \rightarrow A \xrightarrow{f} B \rightarrow 0$ is exact if and only if f is an isomorphism.

(5) A sequence $0 \rightarrow A \xrightarrow{f} B \xrightarrow{g} C$ is exact if and only if f induces $A \xrightarrow{\sim} \ker(g)$.

(6) A sequence $A \xrightarrow{f} B \xrightarrow{g} C \rightarrow 0$ is exact if and only if g induces $\text{coker}(f) \xrightarrow{\sim} C$, where $\text{coker}(f) := B/\text{im}(f)$ is the cokernel of f .

An exact sequence of the form $0 \rightarrow A \xrightarrow{f} B \xrightarrow{g} C \rightarrow 0$ is called a *short exact sequence*. In this case, f induces $A \xrightarrow{\sim} \text{im}(f)$ and g induces $B/\text{im}(f) \xrightarrow{\sim} C$.

Lemma 1.14.3 (Snake lemma). *Consider a commutative diagram of abelian groups with exact rows*

$$(1.14.1) \quad \begin{array}{ccccccc} X' & \longrightarrow & X & \longrightarrow & X'' & \longrightarrow & 0 \\ & & \downarrow u' & & \downarrow u & & \downarrow u'' \\ 0 & \longrightarrow & Y' & \longrightarrow & Y & \longrightarrow & Y'' \end{array}$$

Then we have an exact sequence

$$(1.14.2) \quad \ker(u') \rightarrow \ker(u) \rightarrow \ker(u'') \xrightarrow{\delta} \text{coker}(u') \rightarrow \text{coker}(u) \rightarrow \text{coker}(u''),$$

where the unmarked arrows are induced by the horizontal arrows in (1.14.1) and for each $b \in X$ of image $a \in \ker(u'')$, $\delta(a)$ is the class of $c \in Y'$ whose image in Y is $u(b)$.

The construction of δ is shown by the diagram

$$\begin{array}{ccccc} & & & & a \\ & & & & \downarrow \\ & & & & a \\ & & b & \longrightarrow & a \\ & & \downarrow & & \downarrow \\ & & u(b) & \longrightarrow & 0 \\ c & \longrightarrow & u(b) & \longrightarrow & 0 \\ \downarrow & & & & \\ \delta(a) & & & & \end{array}$$

Proof. It is clear that $\delta(a)$ does not depend on the choice of b . It follows that δ is a homomorphism. One checks the exactness by diagram chasing. \square

Let G be a group, M a G -module. Consider the sequence of abelian groups

$$0 \rightarrow M \xrightarrow{d^0} \text{Map}(G, M) \xrightarrow{d^1} \text{Map}(G^2, M),$$

where $d^1(f): (\sigma, \tau) \mapsto f(\sigma) + \sigma f(\tau) - f(\sigma\tau)$. We have $\ker(d^1) = Z^1(G, M)$ and $\text{im}(d^0) = B^1(G, M)$, so that $\ker(d^1)/\text{im}(d^0) = H^1(G, M)$. Moreover, $\ker(d^0) = M^G$, where

$$M^G = \{m \in M \mid \sigma m = m \text{ for all } \sigma \in G\}.$$

A homomorphism of G -modules is a G -equivariant homomorphism of abelian groups.

Proposition 1.14.4. *Let $0 \rightarrow M' \rightarrow M \rightarrow M'' \rightarrow 0$ be a short exact sequence of G -modules. Then we have a long exact sequence*

$$0 \rightarrow M'^G \rightarrow M^G \rightarrow M''^G \xrightarrow{\delta} H^1(G, M') \rightarrow H^1(G, M) \rightarrow H^1(G, M''),$$

where, for each $x \in M$ of image $y \in M''^G$, $\delta(y)$ is the class of $\sigma \mapsto \sigma(x) - x$ (with $\sigma(x) - x$ regarded as an element of M').

Proof. Applying the snake lemma to the commutative diagram with exact rows

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \text{Map}(G, M') & \longrightarrow & \text{Map}(G, M) & \longrightarrow & \text{Map}(G, M'') & \longrightarrow & 0 \\ & & d^1 \downarrow & & \downarrow d^1 & & \downarrow d^1 & & \\ 0 & \longrightarrow & \text{Map}(G^2, M') & \longrightarrow & \text{Map}(G^2, M) & \longrightarrow & \text{Map}(G^2, M'') & \longrightarrow & 0, \end{array}$$

we obtain an exact sequence $0 \rightarrow Z^1(G, M') \rightarrow Z^1(G, M) \rightarrow Z^1(G, M'')$. We have seen $d^1 d^0 = 0$. Thus we have a commutative diagram with exact rows

$$\begin{array}{ccccccccc} 0 & \longrightarrow & M' & \longrightarrow & M & \longrightarrow & M'' & \longrightarrow & 0 \\ & & d^0 \downarrow & & \downarrow d^0 & & \downarrow d^0 & & \\ 0 & \longrightarrow & Z^1(G, M') & \longrightarrow & Z^1(G, M) & \longrightarrow & Z^1(G, M'') & \longrightarrow & 0. \end{array}$$

We conclude by applying the snake lemma to the above diagram. \square

Kummer theory

Let F be a field and let E be a finite Galois extension of F of group G . Let $n \geq 1$. We have a short exact sequence of G -modules

$$1 \rightarrow \mu_n(E) \rightarrow E^\times \xrightarrow{(-)^n} E^{\times n} \rightarrow 1,$$

which induces the long exact sequence

$$1 \rightarrow \mu_n(F) \rightarrow F^\times \xrightarrow{(-)^n} E^{\times n} \cap F^\times \rightarrow H^1(G, \mu_n(E)) \rightarrow H^1(G, E^\times) = 1.$$

We get an isomorphism $E^{\times n} \cap F^\times / F^{\times n} \xrightarrow{\sim} H^1(G, \mu_n(E))$ carrying the class of x^n , $x \in E^\times$ to the class of $\sigma \mapsto \sigma(x)/x$. Assume now that $\mu_n(E) = \mu_n(F)$. Then G acts trivially on $\mu_n(E)$, so that $H^1(G, \mu_n(E)) = \text{Hom}(G, \mu_n(E))$.

Let us recall the duality for finite abelian groups. Recall that the exponent of a group A is the least common multiple of the orders of $g \in A$. Let C be a cyclic group of order n . For an abelian group A of exponent dividing n , let $A^\vee := \text{Hom}(A, C)$. For A finite, $\#A = \#A^\vee$ and the canonical map $A \rightarrow A^{\vee\vee}$ is an isomorphism. Let A and B be abelian groups of exponent dividing n . A bilinear pairing $A \times B \rightarrow C$ corresponds to homomorphisms $L: A \rightarrow B^\vee$ and $R: B \rightarrow A^\vee$. If A and B are finite, then the following conditions are equivalent:

- (1) L and R are injections.
- (2) L is an isomorphism.
- (3) R is an isomorphism.

In this case, we say that the pairing is *perfect*.

The *exponent* of a Galois extension is defined to be the exponent of its Galois group.

Theorem 1.14.5. *Let $n \geq 1$ be an integer and let F be a field containing a primitive n -th root of unity. Let F^{sep} be a separable closure of F . Then we have a bijection*

$$\begin{aligned} \{F^{\text{sep}}/E/F : E/F \text{ finite abelian of exp. } \mid n\} &\leftrightarrow \{F^{\times n} < \Delta < F^\times : (\Delta/F^{\times n}) < \infty\} \\ E &\mapsto E^{\times n} \cap F^\times \\ F(\sqrt[n]{\Delta}) &\leftarrow \Delta. \end{aligned}$$

Here $F(\sqrt[n]{\Delta}) \subseteq F^{\text{sep}}$ denotes the splitting field of $X^n - y$, $y \in \Delta$. Moreover, for $E \leftrightarrow \Delta$ under the above bijection, the pairing $\text{Gal}(E/F) \times \Delta/F^{\times n} \rightarrow \mu_n(F)$ carrying (σ, \bar{y}) to $\sigma \sqrt[n]{\bar{y}} / \sqrt[n]{\bar{y}}$ is perfect and $[E : F] = (\Delta : F^{\times n})$. Here $y \in \Delta$, \bar{y} denotes its class in $\Delta/F^{\times n}$, and $\sqrt[n]{\bar{y}} \in E$ denotes an n -th root of y .

Note that $X^n - y = \prod_{\zeta \in \mu_n(F)} (X - \zeta \sqrt[n]{y})$.

Proof. The second assertion for $E \mapsto \Delta$ follows from the discussion preceding the theorem.

Let $F^{\times n} < \Delta < F^\times$ such that $[\Delta : F^{\times n}] < \infty$. Then $E_\Delta = F(\sqrt[n]{\Delta})$ is a finite Galois extension of F . The homomorphism $\text{Gal}(E_\Delta/F) \rightarrow \text{Hom}(\Delta/F^{\times n}, \mu_n(F))$ induced by the pairing is clearly injective. It follows that E_Δ/F is an abelian extension of F of exponent dividing n and $[E_\Delta : F] \leq (\Delta : F^{\times n})$. We have $\Delta_{E_\Delta} = E_\Delta^{\times n} \cap F^\times \supseteq \Delta$ and $(\Delta_{E_\Delta} : F^{\times n}) = [E_\Delta : F] \leq (\Delta : F^{\times n})$, which implies that $\Delta_{E_\Delta} = \Delta$ and $[E_\Delta : F] = (\Delta : F^{\times n})$.

Let E/F be a finite abelian extensions of exponent dividing n contained in F^{sep} and let $\Delta_E = E^{\times n} \cap F^\times$. We have $E_{\Delta_E} = F(\sqrt[n]{\Delta_E}) \subseteq E$ and $[E_{\Delta_E} : F] = (\Delta_E : F^{\times n}) = [E : F]$, which implies that $E_{\Delta_E} = E$. \square

Remark 1.14.6. If $E \leftrightarrow \Delta$ and $E' \leftrightarrow \Delta'$ under the bijection above, then $E \cap E' \leftrightarrow \Delta \cap \Delta'$ and $EE' \leftrightarrow \Delta\Delta'$. In fact, by construction, $E \cap E' \mapsto \Delta \cap \Delta'$ and $EE' \leftarrow \Delta\Delta'$.

Example 1.14.7. $E = \mathbb{Q}(\sqrt{2}, \sqrt{-3})$ is an abelian extension of \mathbb{Q} with group $(\mathbb{Z}/2\mathbb{Z})^2$. Indeed, under the above bijection, E corresponds to $\Delta = \langle 2, -3 \rangle \mathbb{Q}^{\times 2}$ and $\Delta/\mathbb{Q}^{\times 2} \simeq (\mathbb{Z}/2\mathbb{Z})^2$.

Corollary 1.14.8. *Assume that F contains a primitive n -th root of unity. Let E/F be a finite cyclic extension of degree n . Then there exists $x \in F$ such that $E = F(\sqrt[n]{x})$. In fact, the equality holds for every $x \in E^{\times n} \cap F^\times$ that is a generator of $E^{\times n} \cap F^\times / F^{\times n}$.*

In order to find x , one may use the *Lagrange resolvent*

$$(\zeta, \alpha) = \sum_{i \in \mathbb{Z}/n\mathbb{Z}} \zeta^i \sigma^i(\alpha),$$

where $\zeta \in \mu_n(F)$, $\alpha \in E$ and $\sigma \in G = \text{Gal}(E/F)$ is a generator. We have $\sigma(\zeta, \alpha) = \zeta^{-1}(\zeta, \alpha)$. It follows that $\sigma(\zeta, \alpha)^n = (\zeta, \alpha)^n$ and $(\zeta, \alpha)^n \in F$. If $(\zeta, \alpha) \neq 0$ for ζ of order m , then $\text{Gal}(E/F((\zeta, \alpha))) = \langle \sigma^m \rangle$, so that $[F((\zeta, \alpha)) : F] = m$. In particular, $E = F((\zeta, \alpha))$ if $(\zeta, \alpha) \neq 0$ for some primitive n -th root of unity ζ .

Proposition 1.14.9. *Assume that F contains a primitive n -th root of unity. Let E/F be a finite cyclic extension with group $\langle \sigma \rangle$ of order n . Then*

- (1) *For every $\zeta \in \mu_n(F)$, there exists $\alpha \in F$ such that $(\zeta, \alpha) \neq 0$.*
- (2) *Assume $n = \ell^m$, where ℓ is a prime, and let $E = F(\beta)$. Then there exists a primitive n -th root of unity ξ such that $(\xi, \beta) \neq 0$ (and hence $E = F((\xi, \beta))$).*

Proof. (1) Let $E = F(\beta)$. We have $((\zeta, \beta^i)) = A(\zeta^j) \neq 0$, where $A = (\sigma^j(\beta^i))$, $0 \leq i, j \leq n-1$ is an invertible matrix.

(2) Fix a primitive n -th root of unity ζ_n . We have

$$\sigma^i(\beta) = \frac{1}{n} \sum_{j \in \mathbb{Z}/n\mathbb{Z}} \zeta_n^{-ij} (\zeta_n^j, \beta).$$

For every nonprimitive n -th root of unity ζ , we have $(\zeta, \beta) \in E^H$, where $H = \langle \sigma^{\ell^{m-1}} \rangle$. If $(\xi, \beta) = 0$ for every primitive n -th root of unity ξ , then $\beta \in E^H$, which contradicts the assumption that $E = F(\beta)$. \square

Example 1.14.10. Let F be a field of characteristic $\neq 2, 3$. Let $P(X) = X^3 + cX + d \in F[X]$ be an irreducible polynomial and let K be its splitting field over F . Let $E = F(\sqrt{D})$, where $D = -4c^3 - 27d^2$ is the discriminant. Write $P(X) = (X - \alpha_1)(X - \alpha_2)(X - \alpha_3)$. We have seen that K/E is a cyclic extension with Galois group $A_3 = \langle \sigma \rangle$, where $\sigma = (123)$. Let $K(\omega)$ be the fraction field of $X^3 - 1$ over K , where $\omega = \frac{1}{2}(-1 + \sqrt{-3})$ is a primitive cube root of unity. Then $K(\omega)/E(\omega)$ is cyclic of group A_3 . Consider the Lagrange resolvent

$$\begin{aligned} (1, \alpha_1) &= \alpha_1 + \alpha_2 + \alpha_3 = 0, \\ \beta_1 &= (\omega, \alpha_1) = \alpha_1 + \omega\alpha_2 + \omega^2\alpha_3, \\ \beta_2 &= (\omega^2, \alpha_1) = \alpha_1 + \omega^2\alpha_2 + \omega\alpha_3. \end{aligned}$$

We have

$$\begin{aligned}\beta_1^3 + \beta_2^3 &= 3\alpha_1 \cdot 3\omega^2\alpha_3 \cdot 3\omega\alpha_2 = -27d, \\ \beta_1\beta_2 &= \alpha_1^2 + \alpha_2^2 + \alpha_3^3 - \alpha_1\alpha_2 - \alpha_2\alpha_3 - \alpha_3\alpha_1 = -3c.\end{aligned}$$

Thus β_1^3 and β_2^3 are the roots of polynomial $Q(X) = X^2 + 27dX - 27c^3$, so that

$$\beta_1^3 = \frac{-27d + \sqrt{-27D}}{2}, \quad \beta_2^3 = \frac{-27d - \sqrt{-27D}}{2}.$$

We get three pairs of values for (β_1, β_2) satisfying $\beta_1\beta_2 = -3c$. Finally,

$$\alpha_1 = \frac{\beta_1 + \beta_2}{3}, \quad \alpha_2 = \frac{\omega^2\beta_1 + \omega\beta_2}{3}, \quad \alpha_3 = \frac{\omega\beta_1 + \omega^2\beta_2}{3}.$$

Artin–Schreier theory

Let F be a field of characteristic $p > 1$. Let E/F be a finite Galois extension with Galois group G . Let $P(X) = X^p - X$. We have a short exact sequence of G -modules

$$0 \rightarrow \mathbb{F}_p \rightarrow E \xrightarrow{P} P(E) \rightarrow 0,$$

which induces the long exact sequence

$$0 \rightarrow \mathbb{F}_p \rightarrow F \xrightarrow{P} P(E) \cap F \rightarrow H^1(G, \mathbb{F}_p) \rightarrow H^1(G, E) = 0.$$

This induces an isomorphism $P(E) \cap F/P(F) \xrightarrow{\sim} \text{Hom}(G, \mathbb{F}_p)$ carrying the class of $P(x)$, $x \in E$ to $\sigma \mapsto \sigma x - x$. The proof of the following theorem is parallel to the proof of Theorem 1.14.5.

Theorem 1.14.11. *Let F^{sep} be a separable closure of F . Then we have a bijection*

$$\begin{aligned}\{F^{\text{sep}}/E/F : E/F \text{ finite abelian of exp. } | p\} &\leftrightarrow \{P(F) < \Delta < F : [\Delta/P(F)] < \infty\} \\ E &\mapsto P(E) \cap F \\ F(P^{-1}(\Delta)) &\leftrightarrow \Delta,\end{aligned}$$

where $F(P^{-1}(\Delta)) \subseteq F^{\text{sep}}$ denotes the splitting field over F of $X^p - X - y$, $y \in \Delta$. Moreover, for $E \leftrightarrow \Delta$ under the above bijection, the pairing $\text{Gal}(E/F) \times \Delta/P(F) \rightarrow \mathbb{F}_p$ carrying $(\sigma, \overline{P(x)})$ to $\sigma x/x$ is perfect and $[E : F] = (\Delta : P(F))$. Here $x \in E$ and $\overline{P(x)}$ denotes the class of $P(x)$ in $\Delta/P(F)$.

Note that $X^p - X - P(x) = \prod_{a \in \mathbb{F}_p} (X - x - a)$.

Witt extended Artin–Schreier theory to cover abelian extensions of exponent a power of p .

1.15 Solvability by radicals

Definition 1.15.1. Let E/F be a finite separable extension.

- (1) We say that E/F is a *radical* extension if there exists a tower of extensions $F = E_0 \subseteq E_1 \subseteq \cdots \subseteq E_m$ such that $E \subseteq E_m$ and that for each $0 \leq i \leq m-1$, $E_{i+1} = E_i(\alpha)$, where one of the following holds
- (a) α is a root of $X^n - a$, $a \in E_i^\times$ and $\text{char}(F) \nmid n$;
 - (b) α is a root of $X^p - X - a$, $a \in E_i$ and $p = \text{char}(F) > 0$.
- (2) We say that E/F is a *solvable* extension if $\text{Gal}(K/F)$ is a solvable group, where K/F is the Galois closure of E/F .

Recall that a group G is said to be *solvable* if there exists a composition series $G = G_0 > G_1 > \cdots > G_m = \{1\}$ such that for every $0 \leq i \leq m-1$, $G_{i+1} \triangleleft G_i$ has abelian quotient. Any subquotient of a solvable group is solvable. It follows that E/F is solvable if and only if there exists a Galois extension K/F containing E with solvable Galois group.

Theorem 1.15.2. *A finite separable extension E/F is solvable if and only if it is radical.*

The implication “solvable \Rightarrow radical” is due to Galois, at least in characteristic 0.

Proof. Radical \Rightarrow solvable. Let $F = E_0 \subseteq E_1 \subseteq \cdots \subseteq E_m$ and $E_{i+1} = E_i(\alpha_i)$ be as in the definition of radical extensions. Let N be the least common multiple of the numbers n appearing in part (a) of the definition. Let ζ be a primitive N -th root of unity in a separable closure of E_m and let L/F be the Galois closure of $E_m(\zeta)/F$. Let $\text{Gal}(L/F) = \{\sigma_1, \dots, \sigma_d\}$. Then L is obtained from F by successively adjoining $\zeta, \sigma_1(\alpha_1), \dots, \sigma_d(\alpha_1), \dots, \sigma_1(\alpha_m), \dots, \sigma_d(\alpha_m)$. We have seen that $L_1 = F(\zeta)/F$ is abelian. Moreover, if α_i is of type (a) (resp. (b)), then by (an easy part of) Kummer (resp. Artin–Schreier) theory applied to $\Delta = \langle a \rangle \cdot L_k^{\times n}$ (resp. $\Delta = \mathbb{Z}a + P(L_k)$, where $P(X) = X^p - X$), $L_{k+1} = L_k(\sigma_j(\alpha_i))/L_k$ is an abelian extension.

Solvable \Rightarrow radical. We may assume that E/F is a solvable Galois extension with Galois group G . There exists a composition series $G = G_0 > G_1 > \cdots > G_m = \{1\}$ such that G_i/G_{i+1} is cyclic of prime order ℓ_i . Consider the corresponding tower of extensions $F = E_0 \subseteq E_1 \subseteq \cdots \subseteq E_m = E$, where $E_i = E^{G_i}$. Let \mathbb{L} be the set of the ℓ_i different from $p = \text{char}(F)$ and let $N = \prod_{\ell \in \mathbb{L}} \ell$. Let ζ be a primitive N -th root of unity in a separable closure of E . Let $E'_i = E_i(\zeta)$. We have $F \subseteq F(\zeta) = E'_0 \subseteq \cdots \subseteq E'_m \supseteq E$. Each E'_{i+1}/E'_i is Galois with $\text{Gal}(E'_{i+1}/E'_i)$ a subgroup of G_{i+1}/G_i and hence is either trivial or cyclic of order ℓ_i . For $\ell_i \neq p$, the extension is of type (a) by Kummer theory (Corollary 1.14.8). For $\ell_i = p$, the extension is of type (b) by Artin–Schreier theory. Thus E/F is radical. \square

We say that a separable polynomial $P(X) \in F[X]$ is *solvable by radicals* over F if its fraction field over F is a radical extension over F . By the theorem, this is equivalent to the condition that the Galois group of $P(X)$ over F is solvable.

Example 1.15.3. (1) For $\deg(P(X)) \leq 4$, since every subgroup of Σ_4 is solvable, $P(X)$ is solvable by radicals.

- (2) Let $P(X) = X^n + T_1X^{n-1} + \cdots + T_n \in F(T_1, \dots, T_n)[X]$ be the generic monic polynomial of degree n . The Galois group of $P(X)$ is Σ_n by Proposition 1.7.12. For $n \geq 5$, Σ_n is not solvable and thus $P(X)$ is not solvable by radicals. This is known as the Abel–Ruffini Theorem.

1.16 Infinite Galois theory

Let I be a partially ordered set.

Definition 1.16.1. A system of sets (resp. groups) $(G_i)_{i \in I}$ indexed by I consists of sets (resp. groups) G_i for all $i \in I$ and transition maps (resp. homomorphisms) $\alpha_{ij}: G_i \rightarrow G_j$ for all $i \leq j$ such that for $i \leq j \leq k$, $\alpha_{jk}\alpha_{ij} = \alpha_{ik}$ and $\alpha_{ii} = \text{id}$. The *limit* (also called projective limit or inverse limit) $\varprojlim_{i \in I} G_i$ of the system is the subset (resp. subgroup) of $\prod_{i \in I} G_i$ consisting of $(g_i \in G_i)$ satisfying $\alpha_{ij}(g_i) = g_j$ for all $i \leq j$.

Let K/F be a Galois extension. We let I denote the set of intermediate fields E such that E/F is a finite Galois extension. We order I by inverse inclusion.

Proposition 1.16.2. *Let K/F be a Galois extension. Then the map*

$$(1.16.1) \quad \text{Gal}(K/F) \rightarrow \varprojlim_{E \in I} \text{Gal}(E/F) \\ \sigma \mapsto (\sigma|_E)_{E \in I},$$

where the transition maps are given by restriction, is a group isomorphism.

Proof. The map is clearly a group homomorphism. For every $\alpha \in K$, the Galois closure of $F(\alpha)/F$ belongs to I . Thus $\bigcup_{E \in I} E = K$. Given an element $(\sigma_E)_{E \in I} \in \varprojlim_{E \in I} \text{Gal}(E/F)$, we define $\sigma \in \text{Gal}(K/F)$ by $\sigma|_E = \sigma_E$. This provides an inverse of (1.16.1). \square

Profinite groups

Definition 1.16.3. A *topological group* is a group G equipped with a topology such that the maps

$$G \times G \rightarrow G \quad (x, y) \mapsto xy \text{ (multiplication)} \\ G \rightarrow G \quad x \mapsto x^{-1} \text{ (inversion)}$$

are continuous. Between two topological groups, a group isomorphism that is a homeomorphism is called an *isomorphism* of topological groups.

Remark 1.16.4. (1) The continuity of the multiplication and inversion maps is equivalent to the continuity of the map $G \times G \rightarrow G$ given by $(x, y) \mapsto x^{-1}y$.

(2) For $x \in G$, the map $l_x: G \rightarrow G$ given by $y \mapsto xy$, called *left translation by x* , is continuous. Moreover, l_x has a continuous inverse $l_{x^{-1}}$, so l_x is a homeomorphism. Similarly, the map $r_x: G \rightarrow G$ given by $y \mapsto yx$ (right translation by x) is a homeomorphism. It follows that G is a *homogeneous space*, in the sense that given $x, y \in G$, there exists a homeomorphism $G \rightarrow G$ sending x to y (for example, $l_{yx^{-1}}$ or $r_{x^{-1}y}$ or $r_y l_x^{-1}$). Thus G looks topologically the same at all points. We can use translations to transfer topological properties from one point to another.

Let H be subgroup of a topological group G . Then H , equipped with the subspace topology, is a topological group.

- Lemma 1.16.5.** (1) Every subgroup H of G containing an open set U of G is open.
 (2) Every open subgroup H of G is closed. Every closed subgroup H of G of finite index is open.
 (3) Every open subgroup H of a compact topological group G has finite index.

Proof. (1) We have $H = \bigcup_{h \in H} hU$.

(2) $H = G - \bigcup_{gH \neq H} gH$ and every left coset gH is open (resp. closed) for H open (resp. closed).

(3) $G = \bigcup_{g \in H} gH$ is an open cover of G and thus admits a finite subcover. \square

Let $(G_i)_{i \in I}$ be a system of finite groups. We equip each G_i with the discrete topology. Then $\prod_{i \in I} G_i$, equipped with the product topology, is a topological group. The subgroup $\varprojlim_{i \in G} G_i$, equipped with the subspace topology, is a topological group.

Definition 1.16.6. A topological group isomorphic to $\varprojlim_{i \in G} G_i$ as above is called a *profinite group*.

Proposition 1.16.7. A profinite group is compact, Hausdorff, and totally disconnected.

A topological space is said to be totally disconnected if every point is a connected component.

Proof. Each G_i is compact, Hausdorff, and totally disconnected. Thus so is $\prod_{i \in I} G_i$ (for the compactness we use Tychonoff's theorem) and its closed subset $\varprojlim_{i \in G} G_i$. \square

Remark 1.16.8. (1) One can show that conversely every compact, Hausdorff, and totally disconnected topological group G is a profinite group. In fact, G is isomorphic to $\varprojlim_{H \in I} G/H$, where I is the set of open subgroups of G , indexed by inclusion [黎, 命题 1.9.3]. The partially ordered set I is cofiltered (see below). Indeed, if H and H' are open normal subgroups of G , then so is $H \cap H'$. Thus every profinite group is isomorphic to a filtered limit of finite groups.

(2) If $G = \varprojlim_{i \in I} G_i$ is a cofiltered limit of finite groups, then the open subgroups $\text{Ker}(G \rightarrow G_i)$, $i \in I$ form a fundamental system of neighborhoods of $e \in G$.

Definition 1.16.9. We say that a partially ordered set J is *filtered* if for all $i, j \in J$, there exists $k \in J$ with $i \leq k$ and $j \leq k$. We say that I is cofiltered if I^{op} is filtered.

The Galois correspondence

Let K/F be a Galois extension. We equip $\text{Gal}(K/F)$ with a topology via the isomorphism (1.16.1). Then $\text{Gal}(K/F)$ is a profinite group, with a fundamental system of neighborhoods of $\text{id}_K \in \text{Gal}(K/F)$ given by $\text{Ker}(\text{Gal}(K/F) \rightarrow \text{Gal}(E/F)) =$

$\text{Gal}(K/E)$, where E runs through finite Galois extensions of F . (The index set in (1.16.1) is cofiltered.)

The profinite group $G = \text{Gal}(K/F)$ acts continuously on K , equipped with the discrete topology. Indeed, the stabilizer of $x \in K$, $\text{Gal}(K/F(x))$, is an open subgroup, since it contains the open subgroup $\text{Gal}(K/E)$, where E/F denotes the Galois closure of $F(x)/F$ in K . For any intermediate field E of K/F , $\text{Gal}(K/E) = \bigcap_{x \in E} \text{Gal}(K/F(x))$ is a closed subgroup of G .

We have the following extension of the finite Galois correspondence.

Theorem 1.16.10. *Let K/F be a Galois extension and let $G = \text{Gal}(K/F)$. Then we have a bijection*

$$\begin{aligned} \{\text{intermediate fields } E \text{ of } K/F\} &\leftrightarrow \{\text{closed subgroups } H < G\} \\ E &\mapsto \text{Gal}(K/E) \\ K^H &\leftarrow H \end{aligned}$$

satisfying the following properties:

- (1) (order-reversal) For $E \leftrightarrow H$ and $E' \leftrightarrow H'$, $E \subseteq E'$ if and only if $H \supseteq H'$. In particular, $E \cap E' \leftrightarrow \overline{\langle HH' \rangle}$ and $EE' \leftrightarrow H \cap H'$.
- (2) (G -equivariance) For $E \leftrightarrow H$ and $\sigma \in G$, $\sigma E \leftrightarrow \sigma H \sigma^{-1}$. In particular, E/F is normal if and only if H is a normal subgroup of G .

Lemma 1.16.11. *Let H be a subgroup of G . Then $\text{Gal}(K/K^H) = \overline{H}$ is the closure of H .*

Proof. $\text{Gal}(K/K^H)$ is a closed subgroup containing H , hence contains \overline{H} . Let $\sigma \in \text{Gal}(K/K^H)$. It suffices to show that for every intermediate field E of K/F with E/F finite Galois, $\sigma \text{Gal}(K/E) \cap H \neq \emptyset$. Let $\phi: \text{Gal}(K/F) \rightarrow \text{Gal}(E/F)$ be the restriction map. Since $\phi(\sigma)$ fixes $E^{\phi(H)} = E \cap K^H$, $\phi(\sigma) \in \phi(H)$ by the fixed field theorem for finite group actions. Thus $\text{Gal}(K/E) \cap H \neq \emptyset$. \square

Proof of Theorem 1.16.10. It remains to show that for every E , $K^{\text{Gal}(K/E)} = E$. Clearly $K^{\text{Gal}(K/E)} \supseteq E$. Conversely, for $x \in K^{\text{Gal}(K/E)}$, let L be the Galois closure of $E(x)/E$ in K , which is a finite extension of E . By the normality of K/E , $\text{Gal}(K/E) \rightarrow \text{Gal}(L/E)$ is a surjection. It follows that $x \in L^{\text{Gal}(L/E)} = E$. \square

Proposition 1.16.12. *For E be an intermediate field of a Galois extension K/F . Let $G = \text{Gal}(K/F)$, $H = \text{Gal}(K/E)$.*

- (1) *we have a bijection*

$$\begin{aligned} \phi: G/H &\xrightarrow{\sim} \text{Hom}_F(E, K) \\ \sigma H &\mapsto \sigma|_E. \end{aligned}$$

- (2) *For E/F normal, the bijection is a group isomorphism $G/H \xrightarrow{\sim} \text{Gal}(E/F)$ and a homeomorphism, where G/H is equipped with the quotient topology.*
- (3) *E/F is finite if and only if H is an open subgroup of G .*

Proof. (1) ϕ is a surjection by Theorem 1.4.3. Moreover, ϕ is an injection, because for $\sigma, \sigma' \in G$, $\sigma|_E = \sigma'|_E$ if and only if $\sigma^{-1}\sigma'|_E = \text{id}_E$.

(2) This is clearly a group homomorphism. Moreover, any continuous bijection from a compact space onto a Hausdorff space is closed, and hence is a homeomorphism.

(3) If E/F is finite, then by (1) $H < G$ is closed of finite index, and hence is open. Conversely, if $H < G$ is open, then $H < G$ has finite index, and by (1) $[E_0 : F] \leq (G : H)$ for any intermediate field E_0 of E/F with E_0/F finite. We conclude by Lemma 1.7.5. \square

Warning 1.16.13. A subgroup of finite index of $\text{Gal}(K/F)$ is not necessarily closed.

For any field F with separable closure F^{sep} , the profinite group $G_F := \text{Gal}(F^{\text{sep}}/F)$ is called the *absolute Galois group* of F . Up to isomorphism G_F does not depend on the choice of F^{sep} . If F^{alg} denotes an algebraic closure of F containing F^{sep} , the restriction map induces a group isomorphism $\text{Aut}_F(F^{\text{alg}}) \xrightarrow{\sim} G_F$. The profinite group $G_{\mathbb{Q}}$ plays a crucial role in number theory.

Example 1.16.14. Let \mathbb{F}_q be a finite field and let $\overline{\mathbb{F}_q}$ be a separable closure. For each $n \geq 1$, we let $\mathbb{F}_{q^n} \subseteq \overline{\mathbb{F}_q}$ denote the unique subfield of order q^n . Then $\overline{\mathbb{F}_q} = \bigcup_{n \geq 1} \mathbb{F}_{q^n}$. We have an isomorphism $\text{Gal}(\mathbb{F}_{q^n}/\mathbb{F}_q) \xrightarrow{\sim} \mathbb{Z}/n\mathbb{Z}$ sending Fr_q to the class of 1. Taking limit, we get an isomorphism of topological groups $G_{\mathbb{F}_q} \simeq \hat{\mathbb{Z}} := \varprojlim_n \mathbb{Z}/n\mathbb{Z}$ sending Fr_q to 1, where the transition maps are given by the projection $\hat{\mathbb{Z}}/n\mathbb{Z} \rightarrow \mathbb{Z}/m\mathbb{Z}$ for $m \mid n$. Here $\hat{\mathbb{Z}}$ is called the profinite completion of \mathbb{Z} .

Example 1.16.15. Let $\overline{\mathbb{Q}}$ be a separable closure of \mathbb{Q} and let $K = \bigcup_n \mathbb{Q}(\zeta_n)$. For each n , we have an isomorphism $\text{Gal}(\mathbb{Q}(\zeta_n)/\mathbb{Q}) \simeq (\mathbb{Z}/n\mathbb{Z})^\times$. Taking limit, we get an isomorphism of topological groups $\text{Gal}(K/\mathbb{Q}) \simeq \hat{\mathbb{Z}}^\times := \varprojlim_n (\mathbb{Z}/n\mathbb{Z})^\times$, where the transition maps are given by the projection $(\mathbb{Z}/n\mathbb{Z})^\times \rightarrow (\mathbb{Z}/m\mathbb{Z})^\times$ for $m \mid n$. By the Kronecker–Weber theorem, $\text{Gal}(K/\mathbb{Q})$ can be identified with the maximal abelian quotient $G_{\text{ab}} = G/\overline{[G, G]}$ (by a closed subgroup) of the absolute Galois group $G = \text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$.

Remark 1.16.16. In fact, $\hat{\mathbb{Z}}$ is a topological ring, namely a ring with continuous subtraction and multiplication, and $\hat{\mathbb{Z}}^\times$ is the group of units of $\hat{\mathbb{Z}}$, equipped with the subspace topology. (In general, for a topological ring R , R^\times equipped with the subspace topology is *not* a topological group.)

Similarly to Remark 1.7.13, one can show that for any profinite group G and any field F , there exists an extension E/F and a Galois extension K/E such that $G \simeq \text{Gal}(K/E)$. On the other hand, not every profinite group is an absolute Galois group.

Theorem 1.16.17 (Artin–Schreier). *Let F be a field such that G_F is finite. Then $\#G_F$ is 1 or 2. More precisely, F is either separably closed or real closed (namely, -1 is not a sum of squares in F and $F(\sqrt{-1})$ is algebraically closed, which implies $\#G_F = 2$ and $\text{char}(F) = 0$).*

For a proof, see [J, §11.7] (combined with the easy fact that $G_F \simeq G_{F^{\text{perf}}}$). For example, \mathbb{R} is a real closed field.

Corollary 1.16.18. *Let F be a field. Then every torsion element σ of G_F has order 1 or 2.*

Proof. This follows from the theorem applied to $(F^{\text{alg}})^{\langle \sigma \rangle}$. \square

It is an open problem to characterize profinite groups isomorphic to G_F .

Warning 1.16.19. Let K be a field and let $G < \text{Aut}(K)$ be a group of automorphisms. Then K/K^G is not necessarily algebraic. For example, if $K = F(X_i)_{i \in \mathbb{Z}}$ and $G = \mathbb{Z}$ acts by translation on the indices, then $K^G = F$. However, we have the following variant of the Fixed Field Theorem.

Proposition 1.16.20. *Let K be a field and let $G < \text{Aut}(K)$ be a group of automorphisms such that K/K^G is algebraic. Then K/K^G is a Galois extension and $G < \text{Gal}(K/K^G)$ is dense.*

Proof. The proof is similar to that of Theorem 1.7.4. Let $x \in K$ and let $O = Gx \subseteq K$. Every $y \in O$ is a root of the minimal polynomial of x over K^G . Thus O is finite and x is a root of $P(X) = \prod_{y \in O} (X - y) \in K^G[X]$. Thus K/K^G is a Galois extension. The density follows from Lemma 1.16.11. \square

Corollary 1.16.21. *Let K/F be an algebraic extension and let $G = \text{Aut}_F(K)$. Then K/K^G is a Galois extension with Galois group G .*

Proof. Since $K^G \supseteq F$, K/K^G is algebraic and the proposition applies. Moreover, $G \subseteq \text{Gal}(K/K^G) \subseteq \text{Aut}_F(K)$, which implies $G = \text{Gal}(K/K^G)$. \square

We deduce the following result on the structure of normal extensions.

Corollary 1.16.22. *Let K/F be a normal extension and let K_{sep} (resp. K_{insep}) be the field of separable (resp. purely inseparable) elements. Then $K = K_{\text{sep}}K_{\text{insep}}$, $K_{\text{insep}} = K^{\text{Aut}_F(K)}$, and K/K_{insep} is a Galois extension.*

Proof. For $x \in K$, the restriction map $\text{Aut}_F(K) \rightarrow \text{Hom}_F(F(x), K)$ is surjective, so that $x \in K^{\text{Aut}_F(K)}$ if and only if $[F(x) : F]_{\text{sep}} = 1$. In other words, $K_{\text{insep}} = K^{\text{Aut}_F(K)}$. Thus, by Corollary 1.16.21, K/K_{insep} is a Galois extension. The extension $K/K_{\text{sep}}K_{\text{insep}}$ is separable and purely inseparable. Thus $K = K_{\text{sep}}K_{\text{insep}}$. \square

1.17 Galois categories

Categories

Definition 1.17.1. A *category* \mathcal{C} consists of a set of *objects* $\text{Ob}(\mathcal{C})$, a set of *morphisms* $\text{Hom}(X, Y)$ for every pair of objects (X, Y) of \mathcal{C} , and a *composition law*, namely a map

$$\text{Hom}(X, Y) \times \text{Hom}(Y, Z) \rightarrow \text{Hom}(X, Z),$$

denoted by $(f, g) \mapsto gf$ (or $g \circ f$), for every triple of objects (X, Y, Z) of \mathcal{C} . These data are subject to the following axioms:

- (associativity) Given morphisms $X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} W$, we have $h(gf) = (hg)f$.

- (unit law) For every object X of \mathcal{C} , there exists an *identity morphism* $\text{id}_X \in \text{End}(X) := \text{Hom}(X, X)$ such that $\text{id}_X f = f$, $\text{id}_X g = g$ for all $f \in \text{Hom}(X, Y)$, $g \in \text{Hom}(Y, X)$.

The morphism id_X is clearly unique.

Remark 1.17.2. For convenience we usually assume that the Hom sets are disjoint. In other words, every morphism $f \in \text{Hom}(X, Y)$ has a unique *source* X and a unique *target* Y .

Remark 1.17.3. Russell’s paradox shows that not every collection is a set. Indeed, the collection R of sets S such that $S \notin S$ cannot be a set, for otherwise $R \in R$ if and only if $R \notin R$. To avoid the paradox, the conventional ZFC (Zermelo–Fraenkel + axiom of choice) set theory does not allow the existence of a set containing all sets or unrestricted comprehension. In category theory, however, it is convenient to introduce a collection of all sets in some sense. In NBG (von Neumann–Bernays–Gödel) set theory, which is an extension of ZFC set theory, one distinguishes between sets and proper classes. Another approach, which we adopt, is to assume the existence of an uncountable Grothendieck universe \mathcal{U} .³ A set in bijection with an element of \mathcal{U} is called a *small set*. The following table loosely summarizes the basic terminological differences of the two approaches.

NBG	class	set	proper class
ZFC + \mathcal{U}	set	small set	large set

We will mostly be interested in categories whose Hom sets are small, which are sometimes called *locally small* categories. A category \mathcal{C} is called *small* if it is locally small and $\text{Ob}(\mathcal{C})$ is small.

Example 1.17.4. (1) Let F be a field.

category	objects (in \mathcal{U})	morphisms
Set	sets	maps
Top	topological spaces	continuous maps
Grp	groups	homomorphisms of groups
Ab	abelian groups	homomorphisms of groups
Vect_F	F -vector spaces	F -linear maps
Field_{/F}	field extensions of F	F -embeddings

In all of the above examples, composition is given by composition of maps.

- (2) The *opposite* category \mathcal{C}^{op} of a category \mathcal{C} is defined by $\text{Ob}(\mathcal{C}^{\text{op}}) = \text{Ob}(\mathcal{C})$ and $\text{Hom}_{\mathcal{C}^{\text{op}}}(X, Y) = \text{Hom}_{\mathcal{C}}(Y, X)$.

Definition 1.17.5. A morphism $f: X \rightarrow Y$ in \mathcal{C} is called an *isomorphism* if there exists a morphism $g: Y \rightarrow X$ such that $gf = \text{id}_X$ and $fg = \text{id}_Y$. The morphism g is unique and is called the *inverse* of f , denoted by f^{-1} .

Remark 1.17.6. The identity map id_X is an isomorphism. Isomorphisms are stable under composition. In particular, $\text{Aut}(X)$ is a group.

³A Grothendieck universe \mathcal{U} is a set satisfying the following conditions: $y \in x \in \mathcal{U}$ implies $y \in \mathcal{U}$; $x, y \in \mathcal{U}$ implies $\{x, y\} \in \mathcal{U}$; $x \in \mathcal{U}$ implies $P(x) \in \mathcal{U}$ where $P(x)$ is the power set of x ; $x_i \in \mathcal{U}$, $i \in I \in \mathcal{U}$ implies $\bigcup_{i \in I} x_i \in \mathcal{U}$. TG (Tarski–Grothendieck) set theory is obtained from ZFC by adding Tarski’s axiom, which states that for every set x , there exists a Grothendieck universe $\mathcal{U} \ni x$.

Example 1.17.7. An isomorphism in **Set** is a bijection. An isomorphism in **Top** is a homeomorphism.

Functors and natural transformations

Definition 1.17.8. Let \mathcal{C} and \mathcal{D} be categories. A functor $F: \mathcal{C} \rightarrow \mathcal{D}$ consists of a map $\text{Ob}(\mathcal{C}) \rightarrow \text{Ob}(\mathcal{D})$ and, for every pair of objects (X, Y) of \mathcal{C} , a map $\text{Hom}_{\mathcal{C}}(X, Y) \rightarrow \text{Hom}_{\mathcal{D}}(FX, FY)$, compatible with composition and identity: $F(\text{id}_X) = \text{id}_{FX}$ for all $X \in \text{Ob}(\mathcal{C})$ and $F(gf) = F(g)F(f)$ for all morphisms $X \xrightarrow{f} Y \xrightarrow{g} Z$.

Example 1.17.9. (1) We have forgetful functors **Top** \rightarrow **Set** and

$$\mathbf{Field}_{/F} \rightarrow \mathbf{Vect}_F \rightarrow \mathbf{Ab} \rightarrow \mathbf{Grp} \rightarrow \mathbf{Set}.$$

(2) We have a functor $D: \mathbf{Vect}_F^{\text{op}} \rightarrow \mathbf{Vect}_F$ carrying V to $V^\vee = \text{Hom}(V, F)$.

Remark 1.17.10. Given functors $F: \mathcal{C} \rightarrow \mathcal{D}$ and $G: \mathcal{D} \rightarrow \mathcal{E}$, we have the composite functor $GF: \mathcal{C} \rightarrow \mathcal{E}$. For any category \mathcal{C} , we have the identity functor $\text{id}_{\mathcal{C}}$. We can thus organize small categories and functors into a category **Cat**.

Definition 1.17.11. Let $F, G: \mathcal{C} \rightarrow \mathcal{D}$ be functors. A *natural transformation* $\alpha: F \rightarrow G$ consists of morphisms $\alpha_X: FX \rightarrow GX$ in \mathcal{D} for all objects X of \mathcal{C} , such that for every morphism $f: X \rightarrow Y$ of \mathcal{C} , the following diagram commutes

$$\begin{array}{ccc} FX & \xrightarrow{Ff} & FY \\ \alpha_X \downarrow & & \downarrow \alpha_Y \\ GX & \xrightarrow{Gf} & GY. \end{array}$$

Example 1.17.12. We have a natural transformation $\text{ev}: \text{id}_{\mathbf{Vect}_F} \rightarrow DD^{\text{op}}$ with $\text{ev}_V: V \rightarrow V^{\vee\vee}$ carrying v to $f \mapsto f(v)$. Here we have identified $(\mathbf{Vect}_F^{\text{op}})^{\text{op}}$ with \mathbf{Vect}_F .

Remark 1.17.13. Given functors $F, G, H: \mathcal{C} \rightarrow \mathcal{D}$ and natural transformations $\alpha: F \rightarrow G$ and $\beta: G \rightarrow H$, we have the (vertically) composite natural transformation $\beta\alpha: F \rightarrow H$. Functors $\mathcal{C} \rightarrow \mathcal{D}$ and natural transformations form a category **Fun**(\mathcal{C}, \mathcal{D}). Isomorphisms in this category are called *natural isomorphisms*⁴. A natural transformation α is a natural isomorphism if and only if α_X is an isomorphism for every object X of \mathcal{C} .

There is also a horizontal composition of natural transformations: Given a natural transformation $\alpha: F \rightarrow G$ between functors $\mathcal{C} \rightarrow \mathcal{D}$ and a natural transformation $\alpha': F' \rightarrow G'$ between functors $\mathcal{D} \rightarrow \mathcal{E}$, we have $\alpha'\alpha: F'F \rightarrow G'G$ between functors $\mathcal{C} \rightarrow \mathcal{E}$. This composition satisfies various compatibilities. Small categories, functors, and natural transformations, together with horizontal and vertical compositions, form a “2-category”.

There is an obvious notion of isomorphism of categories. A more useful notion is the following.

⁴Some authors call them *natural equivalences*.

Definition 1.17.14. An *equivalence of categories* is a functor $F: \mathcal{C} \rightarrow \mathcal{D}$ such that there exists a functor $G: \mathcal{D} \rightarrow \mathcal{C}$ and natural isomorphisms $\text{id}_{\mathcal{C}} \simeq GF$ and $FG \simeq \text{id}_{\mathcal{D}}$.⁵ The functors F and G are then called *quasi-inverses* of each other.

Quasi-inverses of a functor F are unique up to natural isomorphisms.

Remark 1.17.15. Given a composable pair of functors $\mathcal{C} \xrightarrow{F} \mathcal{D} \xrightarrow{G} \mathcal{E}$, if two of F , G , and GF are equivalences of categories, then so is the third one. If $F \rightarrow F'$ is a natural isomorphism of functors, then F is an equivalence of categories if and only if F' is.

Faithful functors, full functors

Definition 1.17.16. A functor $F: \mathcal{C} \rightarrow \mathcal{D}$ is *faithful* (resp. *full*, resp. *fully faithful*) if the map $\text{Hom}_{\mathcal{C}}(X, Y) \rightarrow \text{Hom}_{\mathcal{D}}(FX, FY)$ is an injection (resp. surjection, resp. bijection) for all $X, Y \in \text{Ob}(\mathcal{C})$.

Lemma 1.17.17. *Let $F: \mathcal{C} \rightarrow \mathcal{D}$ be a fully faithful functor.*

- (1) *Let $f: X \rightarrow Y$ be a morphism of \mathcal{C} such that Ff is an isomorphism. Then f is an isomorphism.*
- (2) *Let X and Y be objects of \mathcal{C} such that $FX \simeq FY$. Then $X \simeq Y$.*

Proof. (1) Let g' be an inverse of Ff and let $g: Y \rightarrow X$ be such that $Fg = g'$. Then g is an inverse of f .

(2) Let $f': FX \rightarrow FY$ be an isomorphism and let $f: X \rightarrow Y$ be such that $Ff = f'$. By (1), f is an isomorphism. \square

Remark 1.17.18. There is an obvious notion of *subcategory*. For a subcategory of a category, the inclusion functor is faithful. A *full subcategory* is a subcategory such that the inclusion functor is *fully faithful*.

Example 1.17.19. The category **Ab** is a full subcategory of **Grp**. The forgetful functor $\mathbf{Grp} \rightarrow \mathbf{Set}$ is faithful, but not fully faithful.

Definition 1.17.20. A functor $F: \mathcal{C} \rightarrow \mathcal{D}$ is *essentially surjective* if for every object Y of \mathcal{D} , there exists an object X of \mathcal{C} and an isomorphism $FX \simeq Y$.

Proposition 1.17.21. *A functor $F: \mathcal{C} \rightarrow \mathcal{D}$ is an equivalence of categories if and only if it is fully faithful and essentially surjective.*

Corollary 1.17.22. *Let $F: \mathcal{C} \rightarrow \mathcal{D}$ be a fully faithful functor. Then F induces an equivalence of categories $\mathcal{C} \rightarrow \mathcal{D}_0$, where \mathcal{D}_0 is the full subcategory of \mathcal{D} spanned by the image of F .*

Lemma 1.17.23. *For any category \mathcal{C} , there exists a full subcategory \mathcal{C}_0 such that the inclusion functor $\mathcal{C}_0 \rightarrow \mathcal{C}$ is an equivalence of categories and isomorphic objects in \mathcal{C}_0 are equal.*

⁵Some authors write \simeq for equivalences and \cong for isomorphisms. We will write \simeq for isomorphisms and state equivalences verbally.

Proof. By the axiom of choice, we can pick a representative in each isomorphism class of objects \mathcal{C} . For every object X , pick an isomorphism $\alpha_X: X \xrightarrow{\sim} R_X$, where R_X is the representative of the class of X . Let \mathcal{C}_0 be the full subcategory of \mathcal{C} spanned by the representatives. Consider the functor $F: \mathcal{C} \rightarrow \mathcal{C}_0$ carrying X to R_X and $f: X \rightarrow Y$ to $\alpha_Y f \alpha_X^{-1}: R_X \rightarrow R_Y$. Let $i: \mathcal{C}_0 \rightarrow \mathcal{C}$ be the inclusion functor. Then α_X defines natural isomorphisms $\text{id}_{\mathcal{C}_0} \xrightarrow{\sim} Fi$ and $\text{id}_{\mathcal{C}} \xrightarrow{\sim} iF$. \square

Proof of Proposition 1.17.21. Let F be an equivalence of categories and let G be a quasi-inverse. Since $FG \simeq \text{id}$, F is essentially surjective. Since $GF \simeq \text{id}$, G is essentially surjective. For objects X, X' of \mathcal{C} , since the composition

$$(GF)_{X,X'}: \text{Hom}_{\mathcal{C}}(X, X') \xrightarrow{F_{X,X'}} \text{Hom}_{\mathcal{D}}(FX, FX') \xrightarrow{G_{FX,FX'}} \text{Hom}_{\mathcal{C}}(GFX, GFX')$$

is an isomorphism, $F_{X,X'}$ is an injection. Similarly, for objects Y, Y' of \mathcal{D} , $F_{GY,GY'}$ is a surjection. Since G is essentially surjective, it follows that $F_{X,X'}$ is a surjection.

Now let F be a fully faithful and essentially surjective functor. We apply the lemma to \mathcal{C} and to \mathcal{D} . Let $i: \mathcal{C}_0 \rightarrow \mathcal{C}$ be the inclusion functor and choose a quasi-inverse j' of the inclusion functor $i': \mathcal{D}_0 \rightarrow \mathcal{D}$. Then $j'Fi: \mathcal{C}_0 \rightarrow \mathcal{D}_0$ is fully faithful and essentially surjective, thus a surjection on objects. By Lemma 1.17.17 (2), $j'Fi$ is also an injection on objects. Thus $j'Fi$ is an isomorphism of categories. Since j' and i are equivalences of categories, it follows that F is an equivalence of categories. \square

Galois categories

Let F be a field. We let $\mathbf{Field}_{/F}^{\text{fin,sep}}$ denote the category of separable field extensions of F . The objects are separable field extensions of F and the morphisms are F -embedding.

Let G be a profinite group. We let $G\text{-Set}^{\text{fin}}$ denote the category of finite G -sets. The objects are finite G -sets (namely, discrete sets equipped with a continuous action of G) and the morphisms are G -equivariant maps.

Given a finite separable extension E/F and a separable closure F^{sep}/F , $\text{Hom}_F(E, F^{\text{sep}})$ is equipped with an action of $G_F = \text{Gal}(F^{\text{sep}}/F)$ by composition. The action is continuous. In fact, it factors through the quotient $\text{Gal}(K/F)$, where K is a Galois closure of E in F^{sep} .

Theorem 1.17.24. *The functor*

$$\begin{aligned} (\mathbf{Field}_{/F}^{\text{fin,sep}})^{\text{op}} &\rightarrow G_F\text{-Set}^{\text{fin}} \\ E &\mapsto \text{Hom}_F(E, F^{\text{sep}}) \end{aligned}$$

is fully faithful. Moreover, a finite G_F -set S is isomorphic to an object in the image of the functor if and only if the action of G_F on S is transitive.

Proof. Let E be a finite separable extension of F and let $\iota, \iota': E \rightarrow F^{\text{sep}}$ be F -embedding. Then ι and ι' extend to σ and σ' in G_F , respectively. Then $\iota' = (\sigma'\sigma^{-1})\iota$. Thus the action of G_F on $S_F = \text{Hom}_F(E, F^{\text{sep}})$ is transitive. For a transitive finite G_F -set S , we have $G_F/H \simeq S$ carrying σ to σs , where H is the stabilizer of $s \in S$ and is an open subgroup of G_F . Thus $G_F/H \simeq S_{(F^{\text{sep}})_H}$.

It remains to show the full faithfulness. For finite separable extensions E/F and K/F , we construct an inverse of the map $\alpha: \text{Hom}_F(E, K) \rightarrow \text{Hom}_{G_F}(S_K, S_E)$ as follows. For $\iota \in S_K$, $\iota(K) = (F^{\text{sep}})^{G_\iota}$, where G_ι is the stabilizer of ι . Let $f: S_K \rightarrow S_E$ be a G -equivariant map. Then $G_\iota < G_{f(\iota)}$. Thus $\iota(K) \supseteq f(\iota)(E)$. It follows that there exists a unique embedding $\phi: E \rightarrow K$ such that $\iota\phi = f(\iota)$. Since G acts transitively on S_K , ϕ does not depend on the choice of ι . It is easy to check that $f \mapsto \phi$ is an inverse of α . \square

Definition 1.17.25. A finite product of finite separable field extensions of F is called a *finite étale commutative F -algebra*.

We let $\mathbf{CAlg}_F^{\text{fin.ét}}$ denote the category of finite étale commutative F -algebra. The objects are finite étale commutative F -algebras and the morphisms are homomorphisms of F -algebras. For a finite étale commutative F -algebra $A = \prod_{i=1}^n E_i$ and any field extension K/F , we have $\prod_{i=1}^n \text{Hom}_F(E_i, K) \simeq \text{Hom}_F(A, K)$. Indeed, $A \rightarrow K$ factors through the projection $A \rightarrow E_i$ for a unique i . In particular, $\text{Hom}_F(A, F^{\text{sep}}) = \prod_{i=1}^n \text{Hom}_F(E_i, F^{\text{sep}})$ is a finite G_F -set.

Corollary 1.17.26. *The functor*

$$\begin{aligned} (\mathbf{CAlg}_F^{\text{fin.ét}})^{\text{op}} &\rightarrow G_F\text{-Set}^{\text{fin}} \\ A &\mapsto \text{Hom}_F(A, F^{\text{sep}}) \end{aligned}$$

is an equivalence of categories.

Proof. Again we write S_A for $\text{Hom}_F(A, F^{\text{sep}})$. Every finite G_F -set disjoint union of G_F -orbits. The essential surjectivity of the functor then follows the theorem.

For $B = \prod_{j=1}^m K_j$, $\text{Hom}_F(A, B) \simeq \prod_{j=1}^m \text{Hom}_F(A, K_j)$ and $\text{Hom}_G(S_B, S_A) \simeq \prod_{i=j}^m \text{Hom}_G(S_{K_j}, S_A)$. Thus, to show the full faithfulness, we may assume that $B = K$ is a field. Then, for $A = \prod_{i=1}^n E_i$, $\text{Hom}_F(A, K) \simeq \prod_{i=1}^n \text{Hom}_F(E_i, K)$ and $\text{Hom}_G(S_K, S_A) \simeq \prod_{i=1}^n \text{Hom}_G(S_K, S_{E_i})$, so that we are reduced to the known case where $A = E$ is also a field. \square

Remark 1.17.27. Given a profinite group G , one can recover G from the category $G\text{-Set}^{\text{fin}}$ and the forgetful functor $\Phi: G\text{-Set}^{\text{fin}} \rightarrow \mathbf{Set}^{\text{fin}}$. In fact, one can show that the map $\phi: G \rightarrow \text{Aut}(\Phi)$ with $\phi(g)_S: S \rightarrow S$ given by the action of g is a group isomorphism. Moreover, $\{g \in G \mid \phi(g)_S = \text{id}_S\}$ for varying S form a fundamental system of neighborhoods of $e \in G$.

A *Galois category* is a category equivalent to $G\text{-Set}^{\text{fin}}$ for some profinite group G . Grothendieck gave a characterization of Galois categories [SGA1, §V.4].

1.18 Transcendental extensions

Let E/F be a field extension. The following definition extends the notion of algebraic elements.

Definition 1.18.1. Let $A \subseteq E$ be a subset. We say that A is *algebraically independent over F* if the homomorphism $F[X_a]_{a \in A} \rightarrow E$ carrying X_a to a is injective. (Here $F[X_a]_{a \in A}$ denotes the polynomial ring over F in the indeterminates X_a , $a \in A$.) Otherwise we say that A is *algebraically dependent over F* .

- Remark 1.18.2.** (1) $\{a\}$ is algebraically independent over F if and only if a is transcendental over F .
- (2) A is algebraically dependent over F if there exist distinct elements $a_1, \dots, a_n \in A$ and a polynomial $P(X_1, \dots, X_n) \in F[X_1, \dots, X_n]$ such that $F(a_1, \dots, a_n) = 0$. Thus A is algebraically independent over F if and only if every finite subset of A is.
- (3) A is algebraically independent over F if and only if the above homomorphism extends to an isomorphism $F(X_a)_{a \in A} \xrightarrow{\sim} F(A)$, where $F(X_a)_{a \in A} = \text{Frac}(F[X_a]_{a \in A})$ is the field of rational functions over F in the indeterminates X_a , $a \in A$.

Definition 1.18.3. A field extension E/F generated by a subset $A \subseteq E$ algebraically independent over F is said to be *purely transcendental*.

Lemma 1.18.4. Let E/F be a field extension. A subset $A \amalg B \subseteq E$ is algebraically independent over F if and only if A is algebraically independent over F and B is algebraically independent over $F(A)$.

Proof. If $A \amalg B$ is algebraically independent over F , then clearly A is algebraically independent over F and, by (3), B is algebraically independent over $F(A)$. Conversely, if A is algebraically independent over F and B is algebraically independent over $F(A)$, then we have injections

$$F[X_c]_{c \in A} \amalg B \xrightarrow{X_a \mapsto a} F(A)[X_b]_{b \in B} \xrightarrow[\phi]{X_b \mapsto b} E,$$

so that $A \amalg B$ is algebraically independent over F . □

Proposition 1.18.5. Let E/F be a field extension and let $A \subseteq C \subseteq E$ be subsets such that A is algebraically independent over F . Then there exists a maximal $B \subseteq C$ containing A such that B is algebraically independent over F .

By the lemma, the maximality is equivalent to the condition that every $c \in C$ is algebraic over $F(B)$.

Proof. This follows immediately from Zorn's lemma. Every chain $(B_i)_{i \in I}$ admits an upper bound $\bigcup_{i \in I} B_i$. □

Definition 1.18.6. Let E/F be a field extension. A maximal subset $B \subseteq E$ that is algebraically independent over F is called a *transcendence basis* of E/F .

In other words, a transcendence basis of E/F is a subset $B \subseteq E$ algebraically independent over F such that $E/F(B)$ is algebraic. By the proposition applied to $A = \emptyset$ and $C = E$, a transcendence basis exists.

Remark 1.18.7. (1) Thus any extension E/F can be factorized as a purely transcendental extension $F(B)/F$ and an algebraic extension $E/F(B)$. Such factorizations are *not* unique. For example, $F(X)/F(X^2)$ is an algebraic extension and $F(X^2)/F$ is a purely transcendental extension.

- (2) Given a tower of extensions $K/E/F$. If K/E and E/F are purely transcendental, then K/F is purely transcendental. However, the above example shows that K/F purely transcendental does not imply K/E purely transcendental.

Theorem 1.18.8. *Let B and B' be transcendence bases of a field extension E/F . Then $\text{card}(B) = \text{card}(B')$.*

Lemma 1.18.9 (Exchange property). *Let B and B' be transcendence bases of E/F . Then, for every $b \in B \setminus B'$, there exists $b' \in B' \setminus B$ such that $(B \setminus \{b\}) \cup \{b'\}$ is a transcendence basis.*

Proof. Write $A = B \setminus \{b\}$. If $A \amalg \{b'\}$ is algebraically dependent over F for all $b' \in B' \setminus B$, then $E/F(A)$ is algebraic and A is a transcendence basis, contradicting the assumption that B is a transcendence basis. Thus there exists $b' \in B' \setminus B$ such that $A \amalg \{b'\}$ is algebraically independent over F . Since B is a transcendence basis, $A \amalg \{b, b'\}$ is algebraically dependent over F . It follows that b is algebraic over $F(A \amalg \{b'\})$ and $E/F(A \amalg \{b'\})$ is algebraic. \square

Proof of Theorem 1.18.8. Case where B and B' are finite. By the exchange property applied successively to elements of $B \setminus B'$, there exists a subset $B'' \subseteq B'$ such that $\#B = \#B''$ and that B'' is a transcendence basis for E/F . Thus $B' = B''$.

Case where B or B' is infinite. By symmetry, we may assume that B' is infinite. For each $b \in B$, there exists a finite subset $A_b \subseteq B'$ such that b is algebraic over $F(A_b)$. Let $B'' = \bigcup_{b \in B} A_b \subseteq B'$. Then E is algebraic over B'' , so that $B'' = B'$. Thus B is infinite and $\text{card}(B') \leq \text{card}(B) \cdot \aleph_0 = \text{card}(B)$. By symmetry we also have $\text{card}(B) \leq \text{card}(B')$. \square

Warning 1.18.10. Let E/F be a field extension and let $E_{\text{alg}} \subseteq E$ be the algebraic closure of F in E . Then E/E_{alg} is *not* purely transcendental in general. For example, $E = \bigcup_{n \geq 1} F(X^{1/n})$ is not purely transcendental over F and one can show $E_{\text{alg}} = F$ (see Proposition 1.18.17 below or take F to be algebraically closed).

Definition 1.18.11. The *transcendence degree* of a field extension E/F , denoted by $\text{tr. deg}(E/F)$, is the cardinality of a transcendence basis of E/F .

Proposition 1.18.12. *Let $K/E/F$ be field extensions. Let B be a transcendence basis of E/F and let B' be a transcendence basis of K/E . Then $B \amalg B'$ is a transcendence basis of K/F . In particular,*

$$\text{tr. deg}(K/F) = \text{tr. deg}(K/E) + \text{tr. deg}(E/F).$$

Proof. We have $B \cap B' \subseteq B' \cap E = \emptyset$. We have a tower of algebraic extensions $K/E(B')/F(B \amalg B')$. Moreover, B' is algebraically independent over E and hence over $F(B)$. \square

Proposition 1.18.13. *Let F be a field and let E and E' be algebraically closed extensions of F with $\text{tr. deg}(E/F) = \text{tr. deg}(E'/F)$. Then there exists an F -isomorphism $E \xrightarrow{\sim} E'$.*

Proof. Let B and B' be transcendence bases of E/F and E'/F , respectively. By the assumption on transcendence degree, there exists a bijection $B \xrightarrow{\sim} B'$, which extends uniquely to an F -isomorphism $\phi: F(B) \xrightarrow{\sim} F(B')$. Since E is an algebraic closure of $F(B)$ and E' is an algebraic closure of $F(B')$, ϕ extends to $E \xrightarrow{\sim} E'$. \square

Proposition 1.18.14. *Let F be an infinite field and let E/F be an extension. Then $\text{card}(E) = \max(\text{card}(F), \text{tr. deg}(E/F))$.*

Lemma 1.18.15. (1) *Let R be an infinite commutative domain. Then $\text{card}(\text{Frac}(R)) = \text{card}(R)$.*

(2) *Let R be an infinite ring. Then $\text{card}(R[X_i]_{i \in I}) = \max(\text{card}(R), \text{card}(I))$.*

Proof. (1) We have $R \subseteq \text{Frac}(R)$. Conversely, we have a surjection $R \times (R \setminus \{0\}) \rightarrow \text{Frac}(R)$ carrying (a, b) to a/b .

(2) Let $P = R[X_i]_{i \in I}$. We have an injection $R \cup I \hookrightarrow P$.

Case I finite. We have $P = \bigcup_{d \geq 0} P_d$, where $P_d \subseteq P$ be the subset of polynomials of degree $\leq d$. Then P_d is in bijection with a finite power of R . Thus $\text{card}(P_d) = \text{card}(R)$ and $\text{card}(P) \leq \text{card}(R) \cdot \aleph_0 = \text{card}(R)$.

Assume I infinite. $P = \bigcup_{J \in S} P_J$, where S is the set of finite subsets of I and $P_J = F[X_j]_{j \in J}$. Note that there is an obvious surjection $\prod_{n \geq 0} I^n \rightarrow S$ so that $\text{card}(S) = \text{card}(I)$. By the finite case, $\text{card}(P_J) = \text{card}(R)$. Thus

$$\text{card}(P) \leq \text{card}(S) \cdot \text{card}(R) = \text{card}(I) \cdot \text{card}(R) = \max(\text{card}(R), \text{card}(I)).$$

\square

Proof of Proposition 1.18.14. Let B be a transcendence basis of E/F . By the lemma, $\text{card}(F(B)) = \text{card}(F[B]) = \max(\text{card}(F), \text{card}(B))$.

It remains to show that for an algebraic extension E/F , we have $\text{card}(E) = \text{card}(F)$. The map $\phi: E \rightarrow F[X]$ carrying x to its minimal polynomial has finite fibers. Thus $\text{card}(E) = \text{card}(\text{im}(\phi)) \leq \text{card}(F[X]) = \text{card}(F)$. \square

Example 1.18.16. Let p be a prime number. We let $\mathbb{Q}_p = \text{Frac}(\mathbb{Z}_p)$ denote the field of p -adic numbers, where $\mathbb{Z}_p = \varprojlim_n \mathbb{Z}/p^n\mathbb{Z}$ (where the transition maps are given by projection). Let $\overline{\mathbb{Q}_p}$ be an algebraic closure of \mathbb{Q}_p . Since

$$\text{tr. deg}(\overline{\mathbb{Q}_p}/\mathbb{Q}) = \text{tr. deg}(\mathbb{Q}_p/\mathbb{Q}) = \text{card}(\mathbb{Q}_p) = \text{card}(\mathbb{Z}_p)$$

is the continuum, we have a field isomorphism $\overline{\mathbb{Q}_p} \simeq \mathbb{C}$. Both fields are equipped with natural topologies, but two topological spaces are very different.

Proposition 1.18.17. *Let $K/E/F$ be field extensions with E/F algebraic. Let $A \subseteq K$ be algebraically independent over F . Then A is algebraically independent over E . Moreover, if $S \subseteq E$ is F -linearly independent, then S is $F(A)$ -linearly independent.*

Proof. Since $E(A)/F(A)$ is algebraic, A is a transcendence basis for $E(A)/F$. There exists $B \subseteq A$ such that B is a transcendence basis for $E(A)/E$. Then B is a transcendence basis for $E(A)/F$. It follows that $B = A$.

Assume there exists a nontrivial linear relation $\sum_{s \in S} c_s s = 0$ with $c_s \in F(A)$. We may assume $c_s \in F[A]$ for all $s \in S$, so that the linear relation is an identity in $E[A]$. Since A is algebraically independent over E , taking coefficients in E produces a nontrivial F -linear relation of S . \square

Corollary 1.18.18. *Let $K/E/F$ be a tower of extensions with K/F purely transcendental and E/F algebraic. Then $E = F$.*

Proof. Let S be a linear basis of E/F . By the proposition, S is K -linearly independent. Thus $\#S = 1$. \square

We state the following generalized Lüroth's theorem, due to Gordon in characteristic 0 and to Igusa in general.

Theorem 1.18.19. *Let $K/E/F$ be a tower of extensions with K/F purely transcendental with $\text{tr. deg}(K/F)$ finite and $\text{tr. deg}(E/F) = 1$. Then E/F is purely transcendental.*

There are examples of towers of extensions $K/E/F$ with K/F purely transcendental, $\text{tr. deg}(K/F) = \text{tr. deg}(E/F) = 3$, and E/F not purely transcendental. See [B1] for references.

Proposition 1.18.20. *Let $K/E/F$ be a tower of field extensions. Then K/F is a finitely generated field extension if and only if K/E and E/F are finitely generated field extensions.*

Proof. The only nontrivial part is that if K/F finitely generated, then E/F is finitely generated. We have $\text{tr. deg}(K/F) < \infty$. Up to replacing F by $F(B)$, where B is a transcendence basis of E/F , we may assume that E/F is algebraic. Let B' be a transcendence basis of K/E . Then B' is also a transcendence basis of K/F . By Proposition 1.18.17, $[E : F] \leq [E(B') : F(B')] \leq [K : F(B')] < \infty$. \square

Chapter 2

Modules

2.1 Modules and homomorphisms

Let R be a ring.

Definition 2.1.1. A *left R -module* is an abelian group $(M, +)$ equipped with a map

$$\begin{aligned} R \times M &\rightarrow M \\ (r, m) &\mapsto rm, \end{aligned}$$

called scalar multiplication, satisfying

- (1) $r(m + n) = rm + rn$,
- (2) $r(sm) = (rs)m$,
- (3) $(r + s)m = rm + sm$,
- (4) $1 \cdot m = m$

for all $r, s \in R$ and $m, n \in M$.

In other words, a left R -module is an abelian group $(M, +)$ equipped with a ring homomorphism $R \rightarrow \text{End}(M, +)$.

Remark 2.1.2. Dually, we have an obvious notion of a right R -module, which is the same as a left R^{op} -module. We sometimes write ${}_R M$ for a left R -module M and M_R for a right R -module M . For R commutative, there is no difference between left R -modules and right R -modules.

A *left R -submodule* of a left R -module M is an abelian subgroup N stable under scalar multiplication by R .

Example 2.1.3. (1) The ring R itself is a left R -module, called the left *regular* module. The submodules are called left ideals of R .

- (2) For $R = \mathbb{Z}$, a \mathbb{Z} -module is an abelian group.
- (3) For $R = F$ a field, an F -module is an F -vector space.
- (4) For $S = M_n(R)$ the ring of $n \times n$ matrices in R , R^n , viewed as column vectors, is a left S -module by matrix multiplication.

Definition 2.1.4. Let M and N be left R -modules. A *homomorphism* of left R -modules is a homomorphism of abelian groups $\phi: M \rightarrow N$ satisfying $\phi(rm) = r\phi(m)$ for all $r \in R$ and $m \in M$.

Example 2.1.5. An $R[X]$ -module M is an R -module M equipped with an endomorphism of R -module $X \cdot : M \rightarrow M$.

Given a submodule N of a left R -module M , M/N is a left R -module and the projection map $M \rightarrow M/N$ is a homomorphism of R -modules. We have the following usual properties of homomorphisms, which can be deduced from the corresponding properties of homomorphisms of abelian groups.

Proposition 2.1.6. (1) Let $\phi: M \rightarrow N$ be a homomorphism of left R -modules. Then $\ker(\phi)$ and $\text{im}(\phi)$ are left R -modules and ϕ induces an isomorphism of left R -modules $M/\ker(\phi) \xrightarrow{\sim} \text{im}(\phi)$. In particular, for ϕ surjective, we have $M/\ker(\phi) \simeq N$.

(2) Let M_1 and M_2 be submodules of a left R -module M . Then the inclusion induces an isomorphism of R -modules

$$M_1/(M_1 \cap M_2) \xrightarrow{\sim} (M_1 + M_2)/M_2.$$

(3) Let $\phi: M \rightarrow N$ be a surjective homomorphism of left R -modules. Then there is a bijection

$$\begin{aligned} \{\text{submodules of } M \text{ containing } \ker(\phi)\} &\leftrightarrow \{\text{submodules of } N\} \\ M' &\mapsto \phi(M') \\ \phi^{-1}(N') &\leftarrow N'. \end{aligned}$$

For M' and N' under this bijection, ϕ induces an isomorphism of R -modules $M/M' \simeq N/N'$.

Given a homomorphism $\phi: M \rightarrow N$ of left R -modules, $\text{coker}(\phi) = N/\text{im}(\phi)$ is an R -module. The snake lemma holds for R -modules.

We let $\text{Hom}_R(M, N)$ denote the abelian group of homomorphisms of left R -modules. The abelian group structure is defined by $(\phi + \psi)(m) = \phi m + \psi m$. It is in fact a $Z(R)$ -module, where $Z(R)$ denotes the center of R , by $(r\phi)(m) = r\phi(m)$ for $r \in Z(R)$. Composition of homomorphisms is bi-additive:

$$\phi(\psi_1 + \psi_2) = \phi\psi_1 + \phi\psi_2, \quad (\phi_1 + \phi_2)\psi = \phi_1\psi + \phi_2\psi.$$

In particular, $\text{End}_R(M)$ is a ring.

2.2 Products and direct sums

Let $(M_i)_{i \in I}$ be a family of left R -modules. Then the *product* $\prod_{i \in I} M_i$ is a left R -module: $r(m_i)_{i \in I} = (rm_i)_{i \in I}$. The left R -submodule $\bigoplus_{i \in I} M_i$ consisting of $(m_i)_{i \in I}$ such that $m_i = 0$ for all but finitely many i is called the *direct sum* (or coproduct).

For each i , we have a projection $p_i: \prod_{i \in I} M_i \rightarrow M_i$. Up to isomorphism, the product is characterized by the following universal property: for every left R -module N and every family of morphisms $(f_i: N \rightarrow M_i)_{i \in I}$, there exists a unique morphism $f = (f_i)_{i \in I}: N \rightarrow \prod_{i \in I} M_i$ such that $p_i f = f_i$. This provides an isomorphism of abelian groups

$$\text{Hom}_R(N, \prod_{i \in I} M_i) \simeq \prod_{i \in I} \text{Hom}_R(N, M_i).$$

Similarly, we have

$$\mathrm{Hom}_R\left(\bigoplus_{i \in I} M_i, N\right) \simeq \prod_{i \in I} \mathrm{Hom}_R(M_i, N).$$

Free modules

Definition 2.2.1. Let M be a left R -module and let $A \subseteq M$. We say that A is *linearly independent* (resp. *generating*, resp. *a basis*) if the homomorphism

$$\begin{aligned} R^{\oplus A} &\rightarrow M \\ (r_a)_{a \in A} &\mapsto \sum_{a \in A} r_a a \end{aligned}$$

is injective (resp. surjective, resp. bijective). We say that M is *free* if it admits a basis (or equivalently, if it is isomorphic to a direct sum $R^{\oplus I}$ of copies of R).

We let $\sum_{a \in A} Ra$ denote the submodule generated by $a \in A$. We say that A is *linearly dependent* if it is not linearly independent.

- Remark 2.2.2.**
- (1) Every left R -module M is a quotient of a free module. Indeed, for any generating subset $A \subseteq M$ (for example, M), the map $R^{\oplus A} \rightarrow M$ is a surjection.
 - (2) $\{a\}$ is linearly dependent if and only if a is a torsion element (namely, there exists nonzero $r \in R$ such that $ra = 0$). We say that M is *torsion* if every $m \in M$ is torsion. We say M is *torsionfree* if there is no nonzero torsion elements.
 - (3) A is linearly dependent if and only if every finite subset of A is.
 - (4) $A \amalg B \subseteq M$ is linearly independent if and only if $A \subseteq M$ is linearly independent and $B \subseteq M / \sum_{a \in A} Ra$ is linearly independent.

Proposition 2.2.3. *Let $A \subseteq C \subseteq M$ be such that A is linearly independent. Then there exists a maximal $B \subseteq C$ containing A such that B is linearly independent.*

By the preceding remark, the maximality is equivalent to the condition that the image of every $c \in C$ in $M / \sum_{b \in B} Rb$ is torsion.

Proof. This follows immediately from Zorn's lemma. Every chain $(B_i)_{i \in I}$ admits an upper bound $\bigcup_{i \in I} B_i$. \square

For R nonzero, a basis of M is a maximal linearly independent subset.

A nonzero ring is called a *division ring* if every nonzero element admits an inverse.

Corollary 2.2.4. *If $R = D$ is a division ring, then every left R -module is free.*

Proof. Indeed, every torsion module is zero, so that every maximal linearly independent subset of a module is a basis. We conclude by the proposition. \square

Proposition 2.2.5. *Let $M = \bigoplus_{i \in I} M_i$ with I infinite, where each M_i is a nonzero left R -module. Then every generating subset $S \subseteq M$ satisfies $\mathrm{card}(S) \geq \mathrm{card}(I)$.*

Proof. For each $s \in S$, there exists a finite subset $J_s \subseteq I$ such that $s \in \sum_{j \in J_s} M_j$. Let $J = \bigcup_{j \in J} J_s$. Then $S \subseteq \sum_{j \in J} M_j$. It follows that $J = I$. Thus S is infinite and $\text{card}(I) \leq \text{card}(S) \cdot \aleph_0 = \text{card}(S)$. \square

Corollary 2.2.6. *Let R be a nonzero ring and let A and B be bases of a left R -module M with A infinite. Then $\text{card}(A) = \text{card}(B)$.*

Proof. We have $\text{card}(B) \geq \text{card}(A)$. In particular, B is infinite. By symmetry, we have $\text{card}(A) \geq \text{card}(B)$. \square

The corollary does not extend to the case where both A and B are finite.

Example 2.2.7. Let F be a field and let I be an infinite set. Let $V = F^{\oplus I}$ and let $R = \text{End}_F(V)$. Then $I \simeq I \amalg I$ and $V \simeq V \oplus V$. Applying $\text{Hom}_F(-, V)$, we get $R \simeq R \oplus R$ (as left R -modules).

Definition 2.2.8. We say that a ring R has IBN (Invariant Basis Number) if $R^m \simeq R^n$ as left R -modules implies $m = n$. In this case, for $M \simeq R^{\oplus I}$, we call $\text{card}(I)$ the rank of M and denote it by $\text{rk}_R(M)$.

Remark 2.2.9. (1) A homomorphism $R^m \rightarrow R^n$ of left R -modules is given by an $n \times m$ matrix. Thus R has (left) IBN if and only if every invertible matrix is a square matrix. The same holds for right IBN. Thus having left IBN is equivalent to having right IBN.
 (2) If $R \rightarrow S$ is a ring homomorphism with S having IBN. Then R has IBN. Indeed, a nonsquare invertible matrix over R would give rise to a nonsquare invertible matrix over S .

Example 2.2.10. Nonzero finite rings have IBN. This is clear by comparing cardinalities.

Proposition 2.2.11. *Division rings have IBN.*

Proof. Let D be a division ring and M a left D -module. If B and B' are finite bases of M , then by the exchange property below, there exists $B'' \subseteq B'$ with $\#B = \#B''$ such that B'' is a basis. Thus $B' = B''$. \square

Lemma 2.2.12 (Exchange property). *Let D be a division ring and M a left D -module. Let B be B' be bases of M . Then, for every $b \in B \setminus B'$, there exists $b' \in B' \setminus B$ such that $(B \setminus \{b\}) \cup \{b'\}$ is a basis.*

Proof. Write $A = B \setminus \{b\}$. If $A \amalg \{b'\}$ is linearly dependent for all $b' \in B' \setminus B$, then A is generating and hence is a basis, contradicting the assumption that B is a basis. Thus there exists $b' \in B' \setminus B$ such that $A \amalg \{b'\}$ is linearly independent. Since B is a basis, $A \amalg \{b, b'\}$ is linearly dependent. It follows that $b \in \sum_{a \in A} Da + Db'$ and $A \amalg \{b'\}$ is generating. \square

Corollary 2.2.13. *Nonzero commutative rings R have IBN.*

Proof. Let \mathfrak{m} be a maximal ideal of R . Then the field R/\mathfrak{m} has IBN and we conclude by Remark 2.2.9 (2). \square

Definition 2.2.14. A left R -module is *finitely generated* if it admits a finite generating set. A left R -module is *cyclic* if it admits one generator.

Note that a cyclic module is equivalent to R/I for some left ideal $I \subseteq R$.

2.3 Finitely generated modules over a PID

Let R be a commutative domain. Let M be an R -module. Then the subset $M_{\text{tor}} \subseteq M$ of torsion elements is an R -submodule. Indeed, if $am = 0$ and $bn = 0$ for $a, b \in R$ nonzero, then $ab(m+n) = bam + abn = 0$ and $acm = cam = 0$. The quotient module $M_{\text{tf}} = M/M_{\text{tor}}$ is torsionfree, and is called the *torsionfree quotient* of M .

Remark 2.3.1. A free module over a commutative domain is torsionfree. The converse does not hold: The \mathbb{Z} -module \mathbb{Q} is not free.

Assumption 2.3.2. In the rest of this section (except in Proposition 2.3.10), R is a Principal Ideal Domain (PID).

Proposition 2.3.3. *Let M be a free R -module. Then every R -submodule N of M is free and $\text{rk}_R(N) \leq \text{rk}_R(M)$.*

Proof. Let B be a basis of R . Consider the set P of triples (A, C, f) where $A \subseteq B$ is a subset such that $N_A := N \cap \sum_{a \in A} Ra$ is free, $C \subseteq N_A$ is a basis of N_A , and $f: C \rightarrow A$ is an injection. We equip the set with the following partial order: $(A, C, f) \leq (A', C', f')$ if and only if $A \subseteq A'$, $C \subseteq C'$, and $f'|_C = f$. Then every chain $(A_i, C_i, f_i)_{i \in I}$ in P has an upper bound $(\bigcup_i A_i, \bigcup_i C_i, f)$, where $f|_{C_i} = f_i$. By Zorn's lemma, there exists a maximal element (A, C, f) of P . It suffices to show that $A = B$, so that C is a basis of $N_B = N$ and $\text{card}(C) \leq \text{card}(B)$.

Assume that $A \neq B$. It suffices to show that there exists $(A', C', f') \in P$ with $(A, C, f) \leq (A', C', f')$. Let $b \in B \setminus A$ and let $A' = A \amalg \{b\}$. Consider the ideal $I \subseteq R$ of elements $r \in R$ such that $N \cap (rb + \sum_{a \in A} Ra) \neq \emptyset$. If $I = 0$, then $N_{A'} = N_A$ and we conclude by taking $C' = C$ and $f': C \xrightarrow{f} A \subseteq A'$. Assume $I \neq 0$. Then $I = rR$ with $r \neq 0$. Let $m \in N \cap (rb + \sum_{a \in A} Ra)$. Then $Rm \cap N_A = 0$. Moreover, $N_{A'} \subseteq Ib + \sum_{a \in A} Ra$. Thus $N_{A'} = Rm \oplus N_A$ is free of basis $C' = A \amalg \{m\}$. We define $f': C' \rightarrow A'$ by $f'|_C = f$ and $f'(m) = b$. \square

Remark 2.3.4. (1) A union of free modules is not free in general. For example, for $R = \mathbb{Z}$, $\mathbb{Q} = \bigcup_n \frac{1}{n}\mathbb{Z}$ is not free.
 (2) A maximal linearly independent subset of a free module is not a basis in general. For example, $\{2\} \subseteq \mathbb{Z}$ is not a basis.
 (3) If we only need the freeness of N , it suffices to apply Zorn's lemma to the partially ordered set of pairs (A, C) such that $C \subseteq N_A$ is basis.

Corollary 2.3.5. *Let M be an R -module such that M_{tf} is finitely generated. Then there exists a free submodule of finite rank $L \subseteq M$ such that $M = M_{\text{tor}} \oplus L$.*

Proof. Let $A \subseteq M_{\text{tf}}$ be a finite generating subset and let $B \subseteq A$ be a maximal linearly independent subset. For every $a \in A \setminus B$, $B \amalg \{a\}$ is linearly dependent. In other words, there exists a nonzero $r_a \in R$ such that $r_a a \in \sum_{b \in B} Rb$. Let $r = \prod_{a \in A \setminus B} r_a$. Then multiplication by r gives an injective homomorphism $M_{\text{tf}} \rightarrow \bigoplus_{b \in B} Rb$. By Proposition 2.3.3, M_{tf} is a free module of finite rank. Let C be a basis of M_{tf} . For each $c \in C$, let $\tilde{c} \in M$ be a lifting. Then it suffices to take $L = \sum_{c \in C} R\tilde{c}$. \square

Theorem 2.3.6. *Let F be a free R -module of rank n and let $M \subseteq F$ be a submodule. Then there exist a basis $\{e_1, \dots, e_n\}$ and ideals $I_1 \supseteq I_2 \supseteq \dots \supseteq I_n$ such that $M = \bigoplus_{i=1}^n I_i e_i$. The ideals $I_1 \supseteq I_2 \supseteq \dots \supseteq I_n$ are uniquely determined by F and M and the proper ideals among them are uniquely determined by the isomorphism class of F/M .*

Let $I_i = d_i R$. The nonzero elements in the family $(d_i e_i)$ form a basis of M . The ideals I_i (or the elements d_i) are called the elementary divisors of $M \subseteq F$.

Lemma 2.3.7. *R satisfies the ascending chain condition: given an ascending chain of ideals $I_1 \subseteq I_2 \subseteq \dots$ of R , there exists m such that $I_n = I_m$ for all $n \geq m$.*

Proof. Let $I = \bigcup_i I_i = rR$. There exists m such that $r \in I_m$. Then $I = I_m$. \square

Proof of Theorem 2.3.6. Let us first show the existence by induction on n . By the Lemma, the family $(f(M))_{f \in \text{Hom}_R(F, R)}$ of ideals admits a maximal element, $I_1 = f_1(M)$. If $I_1 = 0$, then $M = 0$ and the existence is clear.

Assume that $I_1 = d_1 R \neq 0$. There exists $x_1 \in M$ be such that $f_1(x_1) = d_1$. For every $f \in \text{Hom}_R(F, R)$, write $f(x_1)R + I_1 = (Rf + Rf_1)(x_1)$ as $rR \supseteq I_1$. There exists $u, v \in R$ such that $(uf + vf_1)(x_1) = r$. By the maximality of I_1 , we have $rR = I_1$, so that $f(x_1) \in I_1$. Thus the coefficients of x_1 under any basis of F are in d_1 . It follows that there exists $e_1 \in F$ such that $x_1 = d_1 e_1$.

By Proposition 2.3.3, $F' = \ker(f_1)$ is free. Since $f_1(e_1) = 1$, every $e \in F$ can be written as $e = f_1(e)e_1 + (e - f_1(e)e_1)$ with $e - f_1(e)e_1 \in F'$ and $F' \cap Re_1 = 0$. Thus $F = Re_1 \oplus F'$. For $m \in M$, $f_1(m)e_1 \in (d_1 R)e_1 = Rx_1 \subseteq M$. Thus $M = I_1 e_1 \oplus M'$, where $M' = M \cap F'$. By induction hypothesis, we obtain a basis $\{e_2, \dots, e_n\}$ of F' and a chain of ideals $I_2 \supseteq \dots \supseteq I_n$ such that $M' = \bigoplus_{i=2}^n I_i e_i$.

For the existence, it remains to show $I_1 \supseteq I_2$. Let $I_2 = d_2 R$ and $I_1 + I_2 = rR$. There exist u and v such that $ud_1 + vd_2 = r$. Let (f_i) be a dual basis of (e_i) :

$$f_i(e_j) = \delta_{ij} = \begin{cases} 1 & i = j \\ 0 & i \neq j. \end{cases}$$

Then $(uf_1 + vf_2)(d_1 e_1 + e_2 d_2) = r$. By the maximality of I_1 , we have $rR = I_1$. In other words, $I_2 \subseteq I_1$.

Next we show the uniqueness. We have $(F/M)_{\text{tor}} \simeq \bigoplus_{I_i \neq 0, R} R/I_i$, $(F/M)_{\text{tf}} \simeq R^k$, where k is the number of zero ideals among (I_i) . Thus, it suffices to show that for $N = \bigoplus_{i=1}^n R/I_i$ with $R \supsetneq I_1 \supseteq \dots \supseteq I_m \neq 0$, (I_i) can be recovered from N . For $I = R \prod_p p^{a_p}$, where p runs through a set of representatives of the equivalence classes of irreducible elements of R and $a_p = 0$ for all but finitely many p , we have

$p^a(R/I)/p^{a+1}(R/I) \simeq \begin{cases} R/pR & a_p > a \\ 0 & a_p \leq a \end{cases}$. Thus, writing $I_i = R \prod_p p^{a_{p,i}}$, we can read off $\#\{i \mid a_{p,i} > a\}$ from $p^a N/p^{a+1} N$. \square

We easily deduce the following structure theorem.

Theorem 2.3.8. *Every finitely generated module N over a PID R is isomorphic to a module of the form $M \simeq \bigoplus_{i=1}^n R/I_i$, where $I_1 \supseteq \dots \supseteq I_n$ is a chain of proper ideals. The chain is uniquely determined by the isomorphism class of N .*

Proof. We write $N = F/M$, where F is a free R -module of finite rank, and apply Theorem 2.3.6. \square

Corollary 2.3.9. *Every finitely generated abelian group A is isomorphic to an abelian group of the form $\bigoplus \mathbb{Z}/d_i\mathbb{Z}$, where $1 \neq d_1 \mid d_2 \mid \cdots \mid d_n$ are nonnegative integers, uniquely determined by the isomorphism class of A .*

In the structure theorem, N_{tor} can be further decomposed. In fact, for $I = R \prod_{i=1}^m p_i^{a_i}$, where p_1, \dots, p_m are pairwise nonassociate irreducible elements of R , we have $R/I \simeq \prod_{i=1}^m R/p_i^{a_i}R$ by the Chinese Remainder Theorem. This decomposition extends to more general rings as follows.

Proposition 2.3.10. *Let $R = \prod_{i \in I} R_i$ be a finite product of rings. For each $i \in I$, consider the bilateral ideal $\mathfrak{a}_i = \prod_{j \in I \setminus \{i\}} R_j$ and the element $e_i = (\delta_{i,j})_{j \in I} \in R$, where*

$$\delta_{i,j} = \begin{cases} 1 & i = j \\ 0 & i \neq j. \end{cases}$$

Let M be a left R -module and let $M_i = M[\mathfrak{a}_i]$. Then we have a decomposition

$$\begin{aligned} \bigoplus_{i \in I} M_i &\xrightarrow{\sim} M \\ (m_i)_{i \in I} &\mapsto \sum_{i \in I} m_i \\ (e_i m)_{i \in I} &\leftarrow m. \end{aligned}$$

For a right ideal \mathfrak{a} of a ring R and a left R -module M , $M[\mathfrak{a}] := \{m \in M \mid \mathfrak{a}m = 0\}$ is a submodule of M , called the \mathfrak{a} -torsion submodule of M . If \mathfrak{a} is a bilateral ideal, then $M[\mathfrak{a}]$ is a (R/\mathfrak{a}) -module. In particular, M_i above is an R_i -module.

Proof. Indeed, $\sum_{i \in I} e_i = 1$ and $e_i m_j = 0$ for $i \neq j$. It follows that $e_j m_j = m_j$. \square

We will often abbreviate bilateral ideals to ideals.

2.4 Chain conditions

Definition 2.4.1. We say that a module M is *Noetherian* if it satisfying the *Ascending Chain Condition* (ACC): for every ascending chain of submodules $M_1 \subseteq M_2 \subseteq \dots$, there exists m such that $M_n = M_m$ for all $n \geq m$. We say that a module M is *Artinian* if it satisfying the *Descending Chain Condition*: for every descending chain of submodules $M_1 \supseteq M_2 \supseteq \dots$, there exists m such that $M_n = M_m$ for all $n \geq m$.

We say that a ring is *left Noetherian* (resp. *left Artinian*) if the regular left R -module R is Noetherian (resp. Artinian). We say that a ring is *right Noetherian* (resp. *right Artinian*) if the regular right R -module R is Noetherian (resp. Artinian). We say that a ring is Noetherian (resp. Artinian) if it is both left and right Noetherian (resp. Artinian).

Remark 2.4.2. M is Noetherian (resp. Artinian) if and only if every set of submodules of M admits a maximal (resp. minimal) element.

Example 2.4.3. (1) Every PID is Noetherian (Lemma 2.3.7). A PID that is not a field is *not* Artinian.

(2) Every division ring D is Noetherian and Artinian. For a left D -module, we have

$$V \text{ is Noetherian} \Leftrightarrow V \text{ is Artinian} \Leftrightarrow V \text{ has finite rank.}$$

(3) Every module of finite cardinality is Noetherian and Artinian.

(4) The \mathbb{Z} -module $\mathbb{Z}[p^{-1}]/\mathbb{Z}$ is Artinian but not Noetherian. In fact, the ascending chain of submodules

$$\mathbb{Z}/\mathbb{Z} \subsetneq p^{-1}\mathbb{Z}/\mathbb{Z} \subsetneq p^{-2}\mathbb{Z}/\mathbb{Z} \subsetneq \dots$$

does not stabilize. On the other hand, every proper submodule has the form $\frac{1}{p^n}\mathbb{Z}/\mathbb{Z}$ for some $n \in \mathbb{Z}_{\geq 0} \cup \{\infty\}$, so that every descending chain of submodules has the form

$$p^{-n_1}\mathbb{Z}/\mathbb{Z} \supseteq p^{-n_2}\mathbb{Z}/\mathbb{Z} \supseteq \dots,$$

where $n_1 \geq n_2 \geq \dots$ stabilizes. However, we will see later that left Artinian rings are left Noetherian.

(5) Let E/F be an infinite field extension. One can show that the ring $\begin{pmatrix} E & E \\ 0 & F \end{pmatrix} \subseteq M_2(E)$ is left Noetherian and left Artinian, but neither right Noetherian nor right Artinian [L2, Corollary 1.24].

(6) Let R be a nonzero ring and let $S = R[X]$ be the polynomial ring. Then S is not left or right Artinian. Indeed, we have the descending chain of ideals

$$S \supseteq SX \supseteq SX^2 \supseteq \dots$$

(7) Let R be a nonzero ring and let $S = R[X_i]_{i \in I}$, where I is an infinite set. Then S is not left or right Noetherian (or Artinian). Indeed, for any sequence i_1, i_2, \dots of elements of I , we have the ascending chain of ideals

$$SX_{i_1} \subseteq SX_{i_1} + SX_{i_2} \subseteq \dots$$

Proposition 2.4.4. Let $0 \rightarrow L \rightarrow M \rightarrow N \rightarrow 0$ be a short exact sequence of modules. Then M is Noetherian (resp. Artinian) if and only if L and N are.

Proof. The “only if” part is clear. To show the “if” part, let (M_i) be an ascending (resp. descending) chain of submodules of M . Let $L_i = L \cap M_i$ and $N_i = (L + M_i)/L$. Then (L_i) and (M_i) stabilize. We have a commutative diagram in the Noetherian case

$$\begin{array}{ccccccc} 0 & \longrightarrow & L_i & \longrightarrow & M_i & \longrightarrow & N_i & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & L_{i+1} & \longrightarrow & M_{i+1} & \longrightarrow & N_{i+1} & \longrightarrow & 0 \end{array}$$

and a similar diagram with vertical arrows reversed in the Artinian case. We conclude by the snake lemma. \square

Corollary 2.4.5. *Let M_1 and M_2 be submodules of M . If both M_1 and M_2 are Noetherian (resp. Artinian), then so is $M_1 + M_2$.*

Proof. Indeed, we have a short exact sequence $0 \rightarrow M_1 \rightarrow M_1 + M_2 \rightarrow (M_1 + M_2)/M_1 \rightarrow 0$ with $(M_1 + M_2)/M_1 \simeq M_2/(M_1 \cap M_2)$. \square

Corollary 2.4.6. *Let R be a left Noetherian (resp. Artinian) ring and let M be a finitely-generated left R -module. Then M is Noetherian (resp. Artinian).*

Proof. Indeed, M is a quotient of R^n for some $n \geq 0$. \square

Proposition 2.4.7. *Let $n \geq 1$. Then a ring R is left Noetherian (resp. Artinian) ring if and only if $S = M_n(R)$ is left Noetherian (resp. Artinian).*

Proof. The regular left S -module is isomorphic to the n -fold product of R^n . Thus S is left Noetherian (resp. Artinian) if and only if the left S -module R^n is. We have seen in the exercises that the submodules of R^n are of the form I^n for some left ideal I of R . Thus ACC (resp. DCC) holds for the regular left R -module if and only if it holds for the left S -module R^n . \square

Proposition 2.4.8. *A module M is Noetherian if and only if every submodule of M is finitely generated.*

Proof. “Only if”: Let $N \subseteq M$ be a submodule. There exists a maximal finitely-generated submodule $N' \subseteq N$. For every $m \in N$, $N + Rm$ is finitely generated, and $N' + Rm = N'$ by the maximality of N' . Thus $N' = N$.

“If”: Let (M_i) be an ascending chain. Then $N = \bigcup_i M_i$ admits a finite generating subset. There exists n such that every $S \subseteq M_n$. Then $M = M_n$. \square

Corollary 2.4.9. *Let R be a left Noetherian ring. Then a left R -module M is Noetherian if and only if it is finitely generated.*

Theorem 2.4.10 (Hilbert basis theorem). *A ring R is left Noetherian if and only if the polynomial ring $R[X]$ is left Noetherian.*

Given a nonzero polynomial $P \in R[X]$, we let $\text{in}(P)$ denote the leading (or initial) coefficient of P . For an additive subgroup $I \subseteq R[X]$, we write $\text{in}_d(I) = \{\text{in}(P) \mid P \in I, \deg(P) = d\} \cup \{0\}$. In other words, $\text{in}_d(I)$ is the image of the homomorphism $I_{\leq d} \rightarrow R$ carrying P to its coefficient of X^d , where $I_{\leq d} \subseteq I$ is the subgroup consisting of polynomials of degree $\leq d$. In particular, if $I \subseteq R[X]$ is a left ideal, then $\text{in}_0(I) \subseteq \text{in}_1(I) \subseteq \dots$ is an ascending chain of left ideals of R .

Lemma 2.4.11. *For additive subgroups $J \subseteq I$ of $R[X]$ such that $\text{in}_d(I) = \text{in}_d(J)$ for all $d \geq 0$, we have $J = I$.*

Proof. Let $P \in I$ be a polynomial of degree d . We proceed by induction on d to show that $P \in J$. The case $d < 0$ is trivial. Assume $d \geq 0$. Then there exists $Q \in J$ of degree d such that P and Q have the same leading coefficients. Then $P - Q \in I$ has degree $< d$, and hence belongs to J by induction hypothesis. It follows that $P \in J$. \square

Proof of Theorem 2.4.10. Since $R \simeq R[X]/(X)$, the “if” part is clear. For the “only if” part, let I be a left ideal of $R[X]$. There exists n such that $\text{in}_d(I) = \text{in}_n(I)$ for $d \geq n$. For each $0 \leq d \leq n$, choose $P_{d,1}, \dots, P_{d,m_d} \in I$ of degree d such that $\{\text{in}(P_{d,j})\}$ generates $\text{in}_d(I)$. Let $J \subseteq R[X]$ be the ideal generated by the finite set $\{P_{d,j}\}_{0 \leq d \leq n, 1 \leq j \leq m_d}$. Then $J \subseteq I$ and $\text{in}_d(J) = \text{in}_d(I)$ for $d \leq n$. The same holds for $d \geq n$. Indeed, for $d \geq n$, $\text{in}_d(J) \supseteq \text{in}_n(J) = \text{in}_n(I) = \text{in}_d(I)$. We conclude by the lemma. \square

Corollary 2.4.12. *Let R be a left Noetherian ring. Then so is the polynomial ring $R[X_1, \dots, X_n]$.*

Let R be a commutative ring. A commutative R -algebra isomorphic to a quotient of $R[X_1, \dots, X_n]$ for some n is called a *finitely generated commutative R -algebra*. A finitely-generated commutative algebra over a Noetherian ring is Noetherian.

Jordan–Hölder Theorem

Definition 2.4.13. We say that a module M is *simple* if it is nonzero and the only submodules are 0 and M .

Remark 2.4.14. If M is a simple module, then any nonzero $m \in M$ is a generator. In particular, simple modules are cyclic. On the other hand, cyclic modules are not simple in general. For example, the \mathbb{Z} -modules \mathbb{Z} and $\mathbb{Z}/4\mathbb{Z}$ are not simple.

Definition 2.4.15. Let M be a module. An (increasing) *filtration* of M of length n is a sequence of inclusions of submodules $0 = M_0 \subseteq M_1 \subseteq \dots \subseteq M_n = M$. The *graded pieces* of the filtration are M_i/M_{i-1} , $1 \leq i \leq n$. We say that two filtrations are equivalent if the graded pieces coincide up to permutation and isomorphism. A filtration of M is called a *composition series* if the graded pieces are simple.

Proposition 2.4.16. *A module admits a composition series if and only if it is both Noetherian and Artinian.*

Proof. Since simple modules are Noetherian and Artinian, the same holds for modules admitting a composition series. Conversely, let M be a Noetherian and Artinian module. If $M = 0$, there exists a unique composition series. Assume $M \neq 0$. Since M is Artinian, there exists a minimal nonzero submodule M_1 of M . Then M_1 is simple. If $M_1 = M$, we get a composition series of M . If not, we repeat the above argument for M/M_1 . This process must stop at some point, providing a composition series of M . Indeed, otherwise we would get an ascending chain of submodules of M , contradicting the assumption that M is Noetherian. \square

Corollary 2.4.17. *Let M be a Noetherian and Artinian module. Then every filtration of M without repetition can be refined to a composition series.*

Proof. Let (M_i) be a filtration without repetition. It suffices to apply the proposition to every subquotient M_i/M_{i-1} and take the preimages in M_i . \square

Theorem 2.4.18 (Jordan–Hölder). *Let M be a module. Any pair of composition series of M are equivalent and hence have the same length.*

Note that any refinement of a composition series is necessarily obtained by repetition. Thus, the Jordan–Hölder theorem follows from the following result.

Theorem 2.4.19 (Schreier refinement theorem). *Any two filtrations of a module M have equivalent refinements.*

Proof. We may assume $M \neq 0$. Let $0 = M_0 \subseteq \cdots \subseteq M_r = M$ and $0 = N_0 \subseteq \cdots \subseteq N_s = M$ be filtrations. For $1 \leq i \leq r$ and $0 \leq j \leq s$, let $M_{i,j} = M_{i-1} + M_i \cap N_j$. For $0 \leq i \leq r$ and $1 \leq j \leq s$, let $N_{i,j} = N_{j-1} + M_i \cap N_j$. Then $0 = M_{1,0} \subseteq \cdots \subseteq M_{1,s} = M_{2,0} \subseteq \cdots \subseteq M_{r-1,s} = M_{r,0} \subseteq \cdots \subseteq M_{r,s} = M$ is a refinement of (M_i) . Similarly, $(N_{i,j})$ is a refinement of (N_i) . For $1 \leq i \leq r$ and $1 \leq j \leq s$, we have $M_{i,j}/M_{i,j-1} \simeq N_{i,j}/N_{i-1,j}$ by the following lemma. \square

Lemma 2.4.20 (Zassenhaus). *Let $M' \subseteq M$ and $N' \subseteq N$ be submodules of a module L . Then we have an isomorphism*

$$\frac{M' + M \cap N}{M' + M \cap N'} \simeq \frac{N' + M \cap N}{N' + M' \cap N}.$$

Proof. We have $M' + M \cap N = (M' + M \cap N') + (M \cap N)$ and $(M' + M \cap N') \cap (M \cap N) = (M' \cap N) + (M \cap N')$. Here in the second equality we used Lemma 2.4.21 below. Thus

$$\frac{M' + M \cap N}{M' + M \cap N'} \simeq \frac{M \cap N}{M' \cap N + M \cap N'}.$$

Similarly,

$$\frac{N' + M \cap N}{N' + M' \cap N} \simeq \frac{M \cap N}{M' \cap N + M \cap N'}.$$

\square

Lemma 2.4.21. *Let $A \subseteq C \subseteq M$ and $A' \subseteq M$ be submodules. Then $(A + A') \cap C = A + A' \cap C$.*

Proof. Clearly $(A + A') \cap C \supseteq A + A' \cap C$. Conversely, every $c \in (A + A') \cap C$ can be written as $c = a + b$ with $a \in A$ and $b \in A'$. Then $b = c - a \in C$. Thus $b \in A' \cap C$. \square

Definition 2.4.22. A Noetherian and Artinian module M is said to be of *finite length*. The length of a composition series of M is called the length of M and denoted by $\text{lg}(M)$. The graded pieces of a composition series are called the *Jordan–Hölder factors* (or *composition factors*) of M . We let $\text{JH}(M)$ denote the multiset of isomorphism classes of Jordan–Hölder factors of M .

Proposition 2.4.23. *Let $0 \rightarrow L \rightarrow M \rightarrow N \rightarrow 0$ be a short exact sequence of modules of finite length. Then $\text{JH}(M) = \text{JH}(L) \cup \text{JH}(N)$. In particular, $\text{lg}(M) = \text{lg}(L) + \text{lg}(N)$.*

Proof. A composition series of L and the preimage of a composition series of N concatenate into a composition series of M . \square

Remark 2.4.24. Let $f: M \rightarrow N$ be a homomorphism of modules of finite length such that $\text{JH}(M) \cap \text{JH}(N) = \emptyset$. Then $f = 0$. Indeed, $\text{JH}(\text{im}(f)) \subseteq \text{JH}(M) \cap \text{JH}(N) = \emptyset$.

2.5 Semisimple modules

Remark 2.5.1. Let R be a ring. A simple left R -module is cyclic, and hence isomorphic to R/I , where $I \subseteq R$ is a maximal left ideal. By a maximal left ideal, we mean a maximal element of the set of proper left ideals.

Proposition 2.5.2. *Let D be a division ring. Then D^n is the unique simple left $M_n(D)$ -module up to isomorphism.*

Proof. Let $R = M_n(D)$. We have seen that the only R -submodules of D^n are 0 and D^n . In other words, D^n is simple. On the other hand, ${}_R R \simeq \bigoplus_{i=1}^n D^n$, so that D^n is the only Jordan–Hölder factor of ${}_R R$. Every simple left R -module is a quotient of ${}_R R$, and hence is isomorphic to D^n . \square

Let R be a ring.

Lemma 2.5.3 (Schur). *Let M and N be simple left R -modules and $f: M \rightarrow N$ a homomorphism. Then either $f = 0$ or f is an isomorphism. In other words, $\text{End}_R(M)$ is a division ring.*

Proof. If $f \neq 0$, then $\ker(f) \neq M$ and $\text{im}(f) \neq 0$. Thus $\ker(f) = 0$ and $\text{im}(f) = N$. \square

Proposition 2.5.4. *Let M_1, \dots, M_r be pairwise nonisomorphic left R -modules and let $M = \bigoplus_{i=1}^r M_i^{\oplus n_i}$. Then $\text{End}_R(M) \simeq \prod_{i=1}^r M_{n_i}(D_i)$, where $D_i = \text{End}_R(M_i)$.*

Proof. By Remark 2.4.24, we are reduced to the trivial case where $r = 1$. \square

Proposition 2.5.5. *For a module M the following conditions are equivalent:*

- (1) M is a sum of simple submodules: $M = \sum_{i \in I} M_i$;
- (2) M is a direct sum of simple submodules: $M = \bigoplus_{i \in I} M_i$;
- (3) Every submodule N of M is a direct summand: there exists a submodule N' of M such that $M = N \oplus N'$.

Moreover, under condition (1), there exists a subset $J \subseteq I$ such that $M = \bigoplus_{j \in J} M_j$.

We call N' in (3) a *complement* of N in M .

Proof. (1) \Rightarrow (2). Let S be the set of $J \subseteq I$ such that $M_J = \sum_{j \in J} M_j$ is a direct sum. For any chain (J_k) in S , $\bigcup_k J_k$ is an upper bound. Indeed, $\sum_{j \in J} M_j$ is a direct sum if and only if $M_j \cap M_{J \setminus \{j\}} = 0$ for all $j \in J$, which can be checked on finite subsets of J . By Zorn's lemma, S admits a maximal element J . Suppose some M_i , $i \in I$ is not contained in M_J . Since M_i is simple, $M_i \cap M_J = 0$ and $J \cup \{i\} \in S$, contradicting the maximality of J . Thus every M_i is contained in M_J and $M = M_J$.

(2) \Rightarrow (3). For $J \subseteq I$, we write $M_J = \bigoplus_{j \in J} M_j$. Let S be the set of $J \subseteq I$ such that $N \cap M_J = 0$. Every chain (J_k) of S has an upper bound $\bigcup_k J_k$. By Zorn's lemma, there exists a maximal $J \subseteq I$. It remains to show that $M = N \oplus M_J$. Let $P = N \oplus M_J$. For each $i \in I$, if $M_i \cap P = 0$, then $N + M_{J \cup \{i\}}$ is a direct sum, contradicting the maximality of J . Thus, since M_i is simple, $M_i \cap P = M_i$. It follows that $P = M$.

(3) \Rightarrow (1). Let N be the sum of all simple submodules of M . Then $M = N \oplus N'$. Assume that $N' \neq 0$. Let C be a nonzero cyclic submodule of N' . By Lemma 2.5.6 below, there exists a maximal proper submodule $A \subseteq C$ with C/A simple. Since B be a direct summand of A in C , which exists by Lemma 2.5.7 below. Then B is simple and $B \subseteq N$, contradicting the assumption $N \cap N' = 0$. Therefore, $N' = 0$ and $M = N$. \square

Lemma 2.5.6. *Every nonzero finitely generated module M admits a simple quotient.*

Proof. Let S be set of proper submodules of M . Every chain (N_i) of S admits an upper bound $\bigcup_i N_i$. Indeed, if $M = \bigcup_i N_i$, then $M = \sum_{j=1}^n Rx_j$ with $x_j \in N_{i_j}$, so that $M = N_{i_k}$ where $k = \max\{i_j\}_j$, contradicting the assumption that each N_i is proper. By Zorn's lemma, S admits a maximal element N . Then M/N is simple. \square

Lemma 2.5.7. *Let $M = A \oplus A'$ and let $A \subseteq C \subseteq M$. Then $C = A \oplus (A' \cap C)$.*

Proof. Clearly $A \cap (A' \cap C) = 0$. Moreover, by Lemma 2.4.21, $C = (A + A') \cap C = A + (A' \cap C)$. \square

Definition 2.5.8. A module satisfying the above conditions is said to be *semisimple*.

Remark 2.5.9. There are ways to associate semisimple modules to more general modules:

- (1) For any module M , the *socle* of M , $\text{soc}(M)$, is the sum of simple submodules of M . This provides a functor soc from the category of modules to the category of semisimple modules.
- (2) For a module M of finite length, the *semisimplification* of M , M_{ss} , is the direct sum of the Jordan–Hölder factors (with multiplicities) of M .

Corollary 2.5.10. *Let $M = \bigoplus_{i \in I} M_i$ with M_i simple and let $N \subseteq M$ be a submodule. Then there exists $J \subseteq I$ such that $M = N \oplus M_J$, where $M_J = \bigoplus_{j \in J} M_j$. In particular, both $N \simeq M_{I \setminus J}$ and $M/N \simeq M_J$ are semisimple.*

Proof. The first assertion follows from the proof of Part (2) \Rightarrow (3) of the proposition. The second assertion is clear. \square

Warning 2.5.11. (1) In the corollary, N is *not* equal to a direct sum of M_i in general. For example, if $M = F^{\oplus 2}$ over a field F and $M_i = Fe_i$, where (e_1, e_2) is the standard basis, then Fv is not equal to M_i for any $v \notin Re_1 \cup Re_2$.
 (2) An infinite product of simple modules is *not* semisimple in general. For example, we have an injection $\mathbb{Z} \rightarrow A = \prod_p \mathbb{Z}/p\mathbb{Z}$, where p runs through prime numbers. Since \mathbb{Z} is not a semisimple \mathbb{Z} -module, neither is A .

Remark 2.5.12. Let M be a semisimple R -module. Then $M = \bigoplus_V M_V$, where V runs through isomorphism classes of simple R -modules, M_V is the image of the map $\text{Hom}_R(V, M) \otimes_{D_V} V \rightarrow M$ given by $f \otimes v \mapsto f(v)$, and $D_V = \text{End}_R(V)$, which is a division ring by Schur's lemma. Here M_V is called the *V -isotypic component* of M . The multiplicity of V in M is $\text{rk}_{D_V} \text{Hom}_R(V, M)$.

2.6 Indecomposable modules

Definition 2.6.1. A ring is called *local* if the set of nonunits I is an ideal.

Note that I is both a maximal left ideal and a maximal right ideal. A local ring is nonzero.

Let R be a ring.

Definition 2.6.2. A left R -module is called *indecomposable* if it is nonzero and is not the direct sum of two nonzero submodules. It is called *strongly indecomposable* if $\text{End}_R(M)$ is a local ring.

Definition 2.6.3. Let R be a ring. An element $e \in R$ is called an *idempotent* if $e^2 = e$.

If e is an idempotent, then $(1 - e)^2 = 1 - 2e + e^2 = 1 - e$ and $e(1 - e) = 0$. An idempotent other than 0 and 1 is a nonunit. A local ring contains exactly two idempotents: 0 and 1.

Proposition 2.6.4. A left R -module M is indecomposable if and only if $\text{End}_R(M)$ contains exactly two idempotents: 0 and 1. In particular, a strongly indecomposable module is indecomposable.

Proof. We may assume $M \neq 0$. Assume $M = N \oplus N'$ with $N, N' \neq 0$. Let e be the projector $M \rightarrow N \hookrightarrow M$. Then $e^2 = e$ and $e \neq 0, 1$. Conversely, if $e \in \text{End}_R(M)$ is an idempotent $\neq 0, 1$, then $M = e(M) \oplus (1 - e)(M)$. \square

Theorem 2.6.5. Let M be an indecomposable module of finite length. Then every endomorphism of M is either nilpotent or an isomorphism. Moreover, M is strongly indecomposable.

The two assertions follow from the two lemmas below.

Lemma 2.6.6 (Fitting). Let M be a module of finite length and let $f: M \rightarrow M$ be an endomorphism. Then there exists a decomposition $M = \ker(f^\infty) \oplus \text{im}(f^\infty)$ such that $f|_{\text{im}(f^\infty)}: \text{im}(f^\infty) \xrightarrow{\sim} \text{im}(f^\infty)$ is an isomorphism and $f|_{\ker(f^\infty)}: \ker(f^\infty) \rightarrow \ker(f^\infty)$ is nilpotent.

Proof. By the chain conditions, there exists n such that $\text{im}(f^m) = \text{im}(f^n)$ and $\ker(f^m) = \ker(f^n)$ for all $m \geq n$. We write $\text{im}(f^\infty) = \text{im}(f^n)$ and $\ker(f^\infty) = \ker(f^n)$.

Let $x = f^n(y)$. If $f^n(x) = 0$, then $y \in \ker(f^{2n}) = \ker(f^n)$ and $x = 0$. Thus $\text{im}(f^\infty) \cap \ker(f^\infty) = 0$.

For any $x \in M$, $f^n(x) \in \text{im}(f^n) = \text{im}(f^{2n})$, so that there exists $y \in M$ such that $f^n(x) = f^{2n}(y)$. Then $x = (x - f^n(y)) + f^n(y) \in \ker(f^\infty) + \text{im}(f^\infty)$.

We have $f|_{\text{im}(f^n)}: \text{im}(f^n) \rightarrow \text{im}(f^{n+1}) = \text{im}(f^n)$ is surjective. Moreover, $\ker(f) \subseteq \ker(f^n)$ has zero intersection with $\text{im}(f^n)$. It follows that $f|_{\text{im}(f^n)}$ is an isomorphism. Moreover, $f(\ker(f^n)) \subseteq \ker(f^n)$ and $f^n|_{\ker(f^n)} = 0$. \square

Lemma 2.6.7. Let R be a nonzero ring such that every $r \in R$ is either nilpotent or invertible. Then R is a local ring.

Note that an element of a nonzero ring cannot be both nilpotent and invertible.

Proof. We need to show that the set N of nilpotent elements of R is an ideal. Let $x \in N$ and $r \in R$. There exists $n \geq 1$ such that $x^n = 0$ but $x^{n-1} \neq 0$. Then $rx(x^{n-1}) = 0 = (x^{n-1})xr$. Thus neither rx nor xr is invertible. It follows that they are nilpotent.

Let $x, y \in N$ and $s = x + y$. If $s \notin N$, then s is invertible and $x = s - y = s(1 - s^{-1}y)$ is invertible. Indeed, $(1 - s^{-1}y)^{-1} = \sum_{i=0}^{\infty} (s^{-1}y)^i$, which is a finite sum, because $s^{-1}y$ is nilpotent. Contradiction. \square

Remark 2.6.8. The set of nilpotent elements in any commutative ring R is obviously an ideal, called the *nilradical* of R and denoted by $\text{nil}(R)$. A commutative ring is said to be *reduced* if $\text{nil}(R) = 0$.

Proposition 2.6.9. *Let M be Noetherian or Artinian module. Then M is a finite direct sum of indecomposable submodules.*

Proof. Assume the contrary. We first treat the Artinian case. Since M is decomposable, $M = M_1 \oplus M'_1$ with $M_i \neq 0$. Either M_1 or M'_1 is not a direct sum of indecomposable modules. We may assume that M'_1 is not. Repeating the argument for M'_1 , we obtain $M'_1 = M_2 \oplus M'_2$ a descending chain (M'_i) that does not stabilize, contradicting the Artinian assumption. The Noetherian case is similar, with $(M_1 + \cdots + M_i)$ being an ascending chain. \square

Decompositions into indecomposable modules are not always unique. However, we have the following result.

Theorem 2.6.10 (Krull–Schmidt–Akizuki). *Let $\bigoplus_{i=1}^m M_i \simeq \bigoplus_{j=1}^n N_j$ be an isomorphism with M_i strongly indecomposable and N_j indecomposable. Then $m = n$ and up to reordering $M_i \simeq N_i$.*

Proof. We may assume $\bigoplus_{i=1}^m M_i = \bigoplus_{j=1}^n N_j$. Let M be the direct sum. We proceed by induction on m . The case $m = 0$ is clear. Assume $m \geq 1$. Consider the morphisms

$$f_j: M_1 \hookrightarrow M \xrightarrow{q_j} N_j \quad g_j: N_j \hookrightarrow M \xrightarrow{p_1} M_1,$$

where q_j and p_1 are the projections. Then $\sum_{j=1}^m g_j f_j = \text{id}_{M_1}$. Since $\text{End}_R(M_1)$ is local, at least one $g_j f_j$ is an isomorphism. Then f_j is an injective homomorphism and, by Lemma 2.6.11 below, its image is a direct summand of N_j . Since N_j is indecomposable, $f_j: M_1 \xrightarrow{\sim} N_j$ is an isomorphism and so is g_j . Up to reordering, we may assume $j = 1$. Since g_1 is an isomorphism and $p_1(\bigoplus_{i=2}^m M_i) = 0$, we have $M = N_1 \oplus (\bigoplus_{i=2}^m M_i) = 0$. Thus $\bigoplus_{i=2}^m M_i \simeq M/N_1 \simeq \bigoplus_{j=2}^n N_j$ and we conclude by induction hypothesis. \square

Lemma 2.6.11. *Let $p: M \rightarrow N$ and $s: N \rightarrow M$ be morphisms of modules such that ps is an isomorphism. Then $M = \ker(p) \oplus \text{im}(s)$ and $s: N \xrightarrow{\sim} \text{im}(s)$.*

Proof. The last assertion follows from the fact that s is an injection. For $m \in \ker(p) \cap \text{im}(s)$, $m = s(n)$ for some $n \in N$ and $0 = p(m) = ps(n)$, which implies $n = 0$ and $m = 0$. For every $m \in M$, $m = (m - s(ps)^{-1}p(m)) + s(ps)^{-1}p(m) \in \ker(p) + \text{im}(s)$. \square

Corollary 2.6.12. *Let M be a module of finite length. Then M admits a decomposition $M \simeq \bigoplus_{i=1}^m M_i$ with M_i indecomposable. Moreover, the M_i are unique up to permutation and isomorphism.*

Proof. We have shown the existence in Proposition 2.6.9. The uniqueness follows from Theorems 2.6.5 and 2.6.10. \square

2.7 Tensor products of modules

Let R be a ring.

Definition 2.7.1. Let M be a right R -module and N a left R -module. Let $(A, +)$ be an abelian group. A map $\phi: M \times N \rightarrow A$ is called a *balanced product* if it satisfies

- (1) $\phi(x + x', y) = \phi(x, y) + \phi(x', y)$;
- (2) $\phi(x, y + y') = \phi(x, y) + \phi(x, y')$;
- (3) $\phi(xr, y) = \phi(x, ry)$

for all $x, x' \in M, y, y' \in N, r \in R$.

Warning 2.7.2. $M \times N$ is an abelian group, but ϕ is *not* a homomorphism of abelian groups unless $2\phi = 0$. In fact, $\phi(2x, 2y) = 4\phi(x, y)$.

Remark 2.7.3. A balanced product can be viewed as an element of

$$\text{Hom}_R(N, \text{Hom}_{\mathbb{Z}}(M, A)) \simeq \text{Hom}_{R^{\text{op}}}(M, \text{Hom}_{\mathbb{Z}}(N, A)).$$

Proposition 2.7.4. *There exist an abelian group $M \otimes_R N$ and a balanced product $\otimes: M \times N \rightarrow M \otimes_R N$ satisfying the following universal property: for every abelian group A and every balanced product $\phi: M \times N \rightarrow A$, there exists a unique group homomorphism $\tilde{\phi}: M \otimes_R N \rightarrow A$ such that $\phi = \tilde{\phi} \circ \otimes$. Moreover, $(M \otimes_R N, \otimes)$ is unique up to unique isomorphism: if $(M \otimes'_R N, \otimes')$ also satisfies the universal property, then there exists a unique isomorphism $f: M \otimes_R N \xrightarrow{\sim} M \otimes'_R N$ such that $\otimes' = f \circ \otimes$.*

We call $M \otimes_R N$ the tensor product of M and N over R . The universal property provides natural isomorphisms

$$\text{Hom}_{\mathbb{Z}}(M \otimes_R N, A) \simeq \text{Hom}_{R^{\text{op}}}(M, \text{Hom}_{\mathbb{Z}}(N, A)) \simeq \text{Hom}_R(N, \text{Hom}_{\mathbb{Z}}(M, A)).$$

Proof. The uniqueness is clear by the universal property. For the existence, we define $M \otimes_R N = F/L$, where F is the free abelian group with basis $M \times N$ and L is the subgroup generated by the elements

$$(x + x', y) - (x, y) - (x', y), \quad (x, y + y') - (x, y) - (x, y'), \quad (xr, y) - (x, ry).$$

We let $x \otimes y$ denote the image of (x, y) in $M \otimes_R N$. The map $\otimes: M \times N \rightarrow M \otimes_R N$ sending (x, y) to $x \otimes y$ is clearly a balanced product. For a balanced product $\phi: M \times N \rightarrow A$, the induced homomorphism $F \rightarrow A$ carrying $(x, y) \mapsto \phi(x, y)$ factors through F/L to give $\tilde{\phi}$. The uniqueness of $\tilde{\phi}$ is clear as $x \otimes y$ generate $M \otimes_R N$. \square

Remark 2.7.5. It follows from the construction that every element of $M \otimes_R N$ can be written noncanonically as a finite sum $\sum_i x_i \otimes y_i$ with $x_i \in M$ and $y_i \in N$.

The universal property implies the functoriality of tensor product: given homomorphisms $f: M_R \rightarrow M'_R$ and $g: {}_R N \rightarrow {}_R N'$, there exists a unique homomorphism of abelian groups $f \otimes_R g: M \otimes_R N \rightarrow M' \otimes_R N'$ such that $(f \otimes_R g)(x \otimes y) = f(x) \otimes g(y)$.

Let R and S be rings.

Definition 2.7.6. An (R, S) -bimodule is an abelian group $(M, +)$ equipped with a left R -module structure and a right S -module structure satisfying $r(ms) = (rm)s$ for all $r \in R$, $s \in S$, $m \in M$.

We sometimes write ${}_R M_S$ for an (R, S) -bimodule M . A homomorphism of bimodules is a homomorphism of left and right modules at the same time.

Example 2.7.7. (1) Given a left R -module M , we equip it with the right A -module structure by $ma = a(m)$, where $a \in A = \text{End}_R(M)^{\text{op}}$. Then M becomes an (R, A) .

(2) Let R be a commutative ring. An R -module M can be regarded as an (R, R) -module by $rxs := rsx$.

Proposition 2.7.8. Let R , S , and T be rings. Let M be an (R, S) -bimodule and N an (S, T) -bimodule. Then there exists a unique (R, T) -bimodule structure on $M \otimes_S N$ such that $r(x \otimes y) = (rx) \otimes y$ and $(x \otimes y)t = x \otimes (yt)$ for all $x \in M$, $y \in N$, $r \in R$, and $t \in T$.

Proof. Indeed, $x \mapsto rx$ is a homomorphism of right S -modules and $y \mapsto yt$ is a homomorphism of left S -module. By the functoriality of tensor product, we obtain a group homomorphism $M \otimes_S N \rightarrow M \otimes_S N$ carrying $x \otimes y$ to $rx \otimes yt$. \square

Remark 2.7.9. Let R be a commutative ring and let M and N be R -modules, regarded as (R, R) -bimodules. Then the (R, R) -bimodule structure on $M \otimes_R N$ comes from an R -bimodule structure. In fact, $r(x \otimes y)s = rx \otimes ys = rx \otimes sy = srx \otimes y = rs(x \otimes y)$.

Remark 2.7.10. Let R , S , T be rings and let ${}_R M_S$, ${}_S N_T$, ${}_R P_T$ be bimodules. We have an isomorphisms of abelian groups

$$\begin{aligned} \text{Hom}_{(R,T)\text{-Mod}}(M \otimes_S N, P) &\simeq \text{Hom}_{(R,S)\text{-Mod}}(M, \text{Hom}_{\text{Mod-}T}(N, P)), \\ &\simeq \text{Hom}_{(S,T)\text{-Mod}}(N, \text{Hom}_{R\text{-Mod}}(M, P)), \end{aligned}$$

The following properties follow easily from the universal property.

Proposition 2.7.11. Let Q , R , S , T be rings and let ${}_Q L_R$, ${}_R M_S$, ${}_S N_T$ be bimodules.

(1) We have $R \otimes_R M \simeq M \simeq M \otimes_S S$ as (R, S) -bimodules.

(2) We have $(L \otimes_R M) \otimes_S N \simeq L \otimes_R (M \otimes_S N)$ as (Q, T) -bimodules.

(3) We have $M \otimes_S N \simeq N \otimes_{S^{\text{op}}} M$ as (R, T) -bimodules.

In (3) we have regarded $(T^{\text{op}}, R^{\text{op}})$ -bimodules as (R, T) -bimodules.

Proposition 2.7.12. Tensor products preserve direct sums and cokernels as follows.

- (1) We have $(\bigoplus_{i \in I} M_i) \otimes_S N \simeq \bigoplus_{i \in I} M_i \otimes_S N$ and $M \otimes_S (\bigoplus_{i \in I} N_i) \simeq \bigoplus_{i \in I} M \otimes_S N_i$.
(2) Exact sequences $M' \rightarrow M \rightarrow M'' \rightarrow 0$ and $N' \rightarrow N \rightarrow N'' \rightarrow 0$ induce exact sequences

$$(2.7.1) \quad M' \otimes_S N \rightarrow M \otimes_S N \rightarrow M'' \otimes_S N \rightarrow 0,$$

$$(2.7.2) \quad M \otimes_S N' \rightarrow M \otimes_S N \rightarrow M \otimes_S N'' \rightarrow 0.$$

This follows from the universal properties of tensor product, direct sum, and cokernel. Let us spell out the universal product of cokernel.

Lemma 2.7.13. *Let $N' \xrightarrow{f} N \xrightarrow{g} N'' \rightarrow 0$ be a sequence of left S -modules satisfying $gf = 0$. Then the sequence is exact if and only if for every left S -module P , the induced sequence*

$$0 \rightarrow \text{Hom}_S(N'', P) \rightarrow \text{Hom}_S(N, P) \rightarrow \text{Hom}_S(N', P)$$

is exact.

To show that (2.7.2) is exact, it suffices to show that for every abelian group A ,

$$0 \rightarrow \text{Hom}(M \otimes_S N'', A) \rightarrow \text{Hom}(M \otimes_S N, A) \rightarrow \text{Hom}(M \otimes_S N', A)$$

is exact. This can be identified with the exact sequence

$$0 \rightarrow \text{Hom}_S(N'', P) \rightarrow \text{Hom}_S(N, P) \rightarrow \text{Hom}_S(N', P),$$

where $P = \text{Hom}(M, A)$.

Remark 2.7.14. The above properties allow us to compute the left R -module $M \otimes_S N$ as follows. Choosing generators and generating relations of the left R -module N , we get $N = \text{coker}({}_S S^{\oplus J} \xrightarrow{f} {}_S S^{\oplus I})$. Then $M \otimes_S N \simeq \text{coker}(M^{\oplus J} \xrightarrow{f_M} M^{\oplus I})$, where f_M is induced from f . In particular, for a left ideal $\mathfrak{a} \subseteq R$, $M \otimes_R R/\mathfrak{a} \simeq M/\mathfrak{a}M$, where $\mathfrak{a}M \subseteq M$ denote the left R -submodule generated by am for $a \in \mathfrak{a}$ and $m \in M$.

Warning 2.7.15. (1) Tensor product does not preserve infinite products in general. For example, $\mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Z}/p\mathbb{Z} = 0$, but $\mathbb{Q} \otimes_{\mathbb{Z}} \prod_p \mathbb{Z}/p\mathbb{Z}$ is not zero. In fact, one can show that $\mathbb{Q} \simeq \mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Z} \hookrightarrow \mathbb{Q} \otimes_{\mathbb{Z}} \prod_p \mathbb{Z}/p\mathbb{Z}$ (because \mathbb{Q} is a flat \mathbb{Z} -module, see below).

- (2) Tensor product does not preserve kernels. For example, $\mathbb{Z} \xrightarrow{\times p} \mathbb{Z}$ is injective, but after tensoring with $\mathbb{Z}/p\mathbb{Z}$ we get $\mathbb{Z}/p\mathbb{Z} \xrightarrow{0} \mathbb{Z}/p\mathbb{Z}$, which is not injective.

Definition 2.7.16. We say that a left S -module N is *flat* if $- \otimes_S N$ preserves kernels.

Chapter 3

Rings and algebras

3.1 Algebras and tensor products

Let R be a commutative ring.

Definition 3.1.1. An R -algebra is a ring A equipped with a ring homomorphism $R \rightarrow Z(A)$, where $Z(A)$ denotes the center of A .

Some authors, notably Bourbaki [B2, III], use the term algebra for a more general notion without identities.

An R -algebra A is equipped with the structure of an R -module. Multiplication in an R -algebra A provides a homomorphism of R -modules $m: A \otimes_R A \rightarrow A$ carrying $a \otimes b$ to ab .

A homomorphism of R -algebras is a ring homomorphism $A \rightarrow B$ that is R -linear.

Tensor product of R -algebras

Let A and B be R -algebras. Then $A \otimes_R B$ is equipped with the structure of an R -algebra satisfying $(a \otimes b)(a' \otimes b') = aa' \otimes bb'$.

Proposition 3.1.2. Let $\iota_A: A \rightarrow A \otimes_R B$ and $\iota_B: B \rightarrow A \otimes_R B$ carrying a to $a \otimes 1$ and b to $1 \otimes b$ respectively. Then $\iota_A(A)$ and $\iota_B(B)$ commute and the triple $(A \otimes B, \iota_A, \iota_B)$ satisfies the following universal property: For every triple (C, f_A, f_B) , where C is an R -algebra and $f_A: A \rightarrow C$ and $f_B: B \rightarrow C$ are homomorphism of R -algebras such that $f_A(A)$ and $f_B(B)$ commute, there exists a unique homomorphism of R -algebras $\phi: A \otimes_R B \rightarrow C$ such that $\phi \iota_A = f_A$ and $\phi \iota_B = f_B$.

Proof. The first assertion is clear. For the second assertion, ϕ is induced by the balanced product $(a, b) \mapsto f_A(a)f_B(b)$. \square

Remark 3.1.3. The homomorphism of R -modules $m: A \otimes_R A \rightarrow A$ is a homomorphism of R -algebras if and only if A is commutative (that is, multiplication in R is commutative). Indeed, $m((a \otimes b)(a' \otimes b')) = aa'bb'$ and $m(a \otimes b)m(a' \otimes b') = aba'b'$.

Remark 3.1.4. The universal property provides a bijection

$$\mathrm{Hom}_{\mathbf{Alg}_R}(A \otimes_R B, C) \xrightarrow{\sim} \mathrm{Hom}_{\mathbf{Alg}_R}(A, C) \times \mathrm{Hom}_{\mathbf{Alg}_R}(B, C)$$

for every commutative R -algebra C . If A and B are commutative R -algebras, then so is $A \otimes_R B$. In this case, $A \otimes_R B$ is the *coproduct* of A and B in the category \mathbf{CAlg}_R .

Remark 3.1.5. If B is a commutative R -algebra, then $A \otimes_R B$ is a B -algebra via ι_B .

Remark 3.1.6. Let S and T be rings. An (S, T) -bimodule is the same as an $(S \otimes_{\mathbb{Z}} T)$ -module.

Let $(A_i)_{i \in I}$ be a family of R -algebras. We define $A_I = \bigotimes_{i \in I} A_i$ by $\varinjlim_J \bigotimes_{j \in J} A_j$, where j runs through finite subsets of I . An element of A_I is a equivalent class of (J, a_J) , where $a_J \in A_J = \bigotimes_{j \in J} A_j$. Two pairs (J, a_J) and $(J', a_{J'})$ are equivalent if and only if there exists $K \supseteq J \cup J'$ such that $\iota_{JK}(a_J) = \iota_{J'K}(a_{J'})$. Here $\iota_J: A_J \rightarrow A_K$ and $\iota_{J'}: A_{J'} \rightarrow A_K$ are induced by the identity elements. Let $\iota_{JI}: A_J \rightarrow A_I$ be the induced homomorphism. We write $\iota_{JI}(\bigoplus_{j \in J} a_j) = \bigotimes_{i \in I} a_i$, where $a_i = 1$ for $i \notin J$.

Remark 3.1.7. If A_i is free as an R -module with basis $S_i \ni 1$, then $\bigotimes_{i \in I} e_i$, with $e_i \in S_i$ for all $i \in I$ and $e_i = 1$ for all but finitely many $i \in I$, form a basis of the R -module A_I . In particular, if each A_i is nonzero and free as an R -module, then so is A_I . We have used this in Lemma 1.4.5.

Linear disjointness

Let E/F and K/F be subextensions of a field extension L/F .

Definition 3.1.8. We say that E and K are *linearly disjoint over F* if the map $m: E \otimes_F K \rightarrow EK$ is an injection.

Remark 3.1.9. The image of m is the subring generated by E and K . Thus EK is the fraction field of the commutative domain $\text{im}(m)$. If E/F or K/F is algebraic, then the image of m is EK . (Indeed, we may assume $E = F[x]$, so that $\text{im}(m) = K[x] = EK$.) In this case, E and K are linearly disjoint if and only if $E \otimes_F K$ is a field. Note that the last condition is independent of the choice of L .

Remark 3.1.10. If E and K are linearly disjoint over F , then EK is the fraction field of $E \otimes_F K$, and thus is independent of L (or the embeddings $E \subseteq L$ and $K \subseteq L$) up to isomorphisms.

Proposition 3.1.11. *The following conditions are equivalent:*

- (1) E and K are linearly disjoint over F .
- (2) Every subset S of E that is F -linearly independent is K -linearly independent.
- (3) Every subset T of K that is F -linearly independent is E -linearly independent.

Proof. By symmetry it suffices to show (1) \Leftrightarrow (2). Let $V = \bigoplus_{s \in S} Es$. Consider the map $K^{\oplus S} \simeq V \otimes_F K \xrightarrow{i} E \otimes_F K \xrightarrow{m} EK$ carrying $(a_s)_{s \in S}$ to $\sum_{s \in S} a_s s$. Since V is a direct summand of E , i is an injection. Thus if m is an injection, then the composite is an injection. Conversely, taking S to be a basis of E , then the injectivity of the composite implies the injectivity of m . \square

Example 3.1.12. If E/F is algebraic and K/F is purely transcendental, then they are linearly disjoint by Proposition 1.18.17.

Example 3.1.13. If E/F is separable and K/F is purely inseparable, then they are linearly disjoint. Indeed, we may assume that E/F and K/F are finite. Then $[EK : F]_{\text{sep}} \geq [E : F]_{\text{sep}} = [E : F]$ and $[EK : F]_{\text{insep}} \geq [K : F]_{\text{insep}} = [K : F]$. The map $m: E \otimes_F K \rightarrow EK$ is surjective with $\dim_F(E \otimes_F K) \leq \dim_F(EK)$. It follows that m is an isomorphism.

Tensor algebra

Let M be an R -module. For $n \geq 0$, we write $T^n(M) = M^{\otimes n} = M \otimes_R \cdots \otimes_R M$ (where M is repeated n times). By convention $T^0(M) = R$. We have canonical isomorphisms $m_{i,j}: T^i(M) \otimes_R T^j(M) \xrightarrow{\sim} T^{i+j}(M)$ carrying $(x_1 \otimes \cdots \otimes x_i) \otimes (y_1 \otimes \cdots \otimes y_j)$ to $x_1 \otimes \cdots \otimes x_i \otimes y_1 \otimes \cdots \otimes y_j$.

Definition 3.1.14. We call $T(M) = \bigoplus_{n=0}^{\infty} T^n(M)$ the *tensor algebra* of the R -module M . The multiplication is induced by $m_{i,j}$ and the identity element is $1 \in R = T^0(M)$.

Let $i: M = T^1(M) \hookrightarrow T(M)$ be the inclusion.

Proposition 3.1.15 (Universal property for the tensor algebra). *For every R -algebra A equipped with a homomorphism of R -modules $f: M \rightarrow A$, there exists a unique homomorphism of R -algebras $T(M) \rightarrow A$ such that $f = \phi i$.*

We have a natural isomorphism $\text{Hom}_{\mathbf{Alg}_R}(TM, A) \simeq \text{Hom}_{R\text{-Mod}}(M, UA)$, where $U: \mathbf{Alg}_R \rightarrow R\text{-Mod}$ denotes the forgetful functor. In other words, T is a *left adjoint* to the forgetful functor U .

Proof. Indeed, $\phi|_{T^n(M)}$ is given by the R -multilinear map $M^n \rightarrow A$ carrying (x_1, \dots, x_n) to $f(x_1) \cdots f(x_n)$. \square

Definition 3.1.16. Let $I_{\text{Sym}}(M)$ denote the ideal of $T(M)$ generated by $x \otimes y - y \otimes x$, $x, y \in M$ and let $I_{\wedge}(M)$ denote the ideal of $T(M)$ generated by $x \otimes x$, $x \in M$. We call $\text{Sym}(M) = T(M)/I_{\text{Sym}}(M)$ the *symmetric algebra* of the R -module M and $\wedge(M) = T(M)/I_{\wedge}(M)$ the *exterior algebra* of the R -module M .

Since both ideals are generated by homogeneous elements, we have

$$I_{\text{Sym}}(M) = \bigoplus_{n=0}^{\infty} I_{\text{Sym}}^n(M), \quad I_{\wedge}(M) = \bigoplus_{n=0}^{\infty} I_{\wedge}^n(M),$$

where $I_{\text{Sym}}^n(M) = I_{\text{Sym}}(M) \cap T^n(M)$ and $I_{\wedge}^n(M) = I_{\wedge}(M) \cap T^n(M)$. It follows that

$$\text{Sym}(M) = \bigoplus_{n=0}^{\infty} \text{Sym}^n(M), \quad \wedge(M) = \bigoplus_{n=0}^{\infty} \wedge^n(M),$$

where $\text{Sym}^n(M)$ (resp. $\wedge^n(M)$) is the image of $T^n(M)$ in $\text{Sym}(M)$ (resp. $\wedge(M)$).

We denote the product in $\text{Sym}(M)$ by $(x, y) \mapsto xy$ and the product in $\wedge(M)$ by $(x, y) \mapsto x \wedge y$. It is easy to see that $\text{Sym}(M)$ is a commutative algebra. For $x, y \in M$,

$(x + y) \otimes (x + y) - x \otimes x - y \otimes y = x \otimes y + y \otimes x \in I_\wedge(M)$, so that $x \wedge y = y \wedge x$. It follows that $\wedge(M)$ satisfies the Koszul sign convention: For $x \in \wedge^i(M)$, $y \in \wedge^j(M)$, we have $x \wedge y = (-1)^{ij}y \wedge x$.

We have $\text{Sym}^n(M) = T^n(M)$ and $\wedge^n(M) = T^n(M)$ for $n \leq 1$. The universal property for the tensor algebra implies the following.

- Proposition 3.1.17** (Universal properties). (1) For every commutative R -algebra A and every homomorphism of R -modules $f: M \rightarrow A$, there exists a unique homomorphism of R -algebras $\phi: \text{Sym}(M) \rightarrow A$ such that $f = \phi i$, where $i: M = \text{Sym}^1(M) \hookrightarrow \text{Sym}(M)$ is the inclusion.
- (2) For every R -algebra A and every homomorphism of R -modules $f: M \rightarrow A$ such that $f(x)^2 = 0$ for every $x \in M$, there exists a unique homomorphism of R -algebras $\phi: \wedge(M) \rightarrow A$ such that $f = \phi i$, where $i: M = \wedge^1(M) \hookrightarrow \wedge(M)$ is the inclusion.

By (1), we have a natural isomorphism $\text{Hom}_{\mathbf{CAlg}_R}(\text{Sym}(M), A) \simeq \text{Hom}_{R\text{-Mod}}(M, UA)$, where $U: \mathbf{CAlg}_R \rightarrow R\text{-Mod}$ denotes the forgetful functor.

The universal properties for the tensor product of modules $T^n(M)$ induces the following universal properties for the R -modules $\text{Sym}^n(M)$ and $\wedge^n(M)$. We say that an R -multilinear map $\phi: M^n \rightarrow N$ is *symmetric* (resp. *alternating*) if $\phi(\dots, x, y, \dots) = \phi(\dots, y, x, \dots)$ (resp. $\phi(\dots, x, x, \dots) = 0$) for $x, y \in M$.

- Proposition 3.1.18.** (1) Let N be an R -module and $\phi: M^n \rightarrow N$ a symmetric R -multilinear map. Then there exists a unique homomorphism of R -modules $\tilde{\phi}: \text{Sym}^n(M) \rightarrow N$ such that $\phi = \tilde{\phi} p$, where $p: M^n \rightarrow \text{Sym}^n(M)$ is the map carrying (x_1, \dots, x_n) to $x_1 \cdots x_n$.
- (2) Let N be an R -module and $\phi: M^n \rightarrow N$ an alternating R -multilinear map. Then there exists a unique homomorphism of R -modules $\tilde{\phi}: \wedge^n(M) \rightarrow N$ such that $\phi = \tilde{\phi} p$, where $p: M^n \rightarrow \wedge^n(M)$ is the map carrying (x_1, \dots, x_n) to $x_1 \wedge \cdots \wedge x_n$.

Example 3.1.19. Let M be a free R -module of basis S . Then $T(M) = R\langle S \rangle$ is the free R -algebra generated by S and $\text{Sym}(M) = R[S]$ is the polynomial R -algebra on S . For any total order on S , $\wedge^n(M)$ is a free R -module with basis $x_1 \wedge \cdots \wedge x_n$, where $x_1 < \cdots < x_n$ in S .

The symmetric group Σ_n acts on $T^n(M)$ by $\sigma(x_1 \otimes \cdots \otimes x_n) = x_{\sigma^{-1}(1)} \otimes \cdots \otimes x_{\sigma^{-1}(n)}$. For every group homomorphism $\chi: \Sigma_n \rightarrow \{\pm 1\}$, we define $T_\chi^n(M) = \{x \in T^n(M) \mid \sigma(x) = \chi(\sigma)x, \forall \sigma \in \Sigma_n\}$ and let $T_\chi(M) = \bigoplus_{n=0}^\infty T_\chi^n(M)$. We call elements of $T_{\text{Sym}}(M) := T_1(M)$ *symmetric tensors* and elements of $T_\wedge(M) := T_{\text{sgn}}(M)$ *skewsymmetric tensors*.

Consider the compositions

$$\phi_1: T_{\text{Sym}}^n(M) \hookrightarrow T^n(M) \xrightarrow{q_1} \text{Sym}^n(M), \quad \phi_{\text{sgn}}: T_\wedge^n(M) \hookrightarrow T^n(M) \xrightarrow{q_{\text{sgn}}} \wedge^n(M).$$

Let $p_\chi = \sum_{\sigma \in \Sigma_n} \chi(\sigma)\sigma: T^n(M) \rightarrow T^n(M)$. Then $\tau p_\chi = p_\chi \tau = \chi(\tau)p_\chi$. Thus $\text{im}(p_\chi) \subseteq T_\chi^n(M)$.

We have $I_{\text{Sym}}^n(M) \subseteq \sum_{\sigma \in \Sigma_n} \text{im}(\sigma - 1) \subseteq \ker(p_1)$, so that p_1 factorizes through a unique homomorphism $\psi_1: \text{Sym}^n(M) \rightarrow T_{\text{Sym}}^n(M)$. We have $\psi_1 \phi_1 = n! \cdot \text{id}$ and $\phi_1 \psi_1 = n! \cdot \text{id}$.

If 2 is invertible in R , then $I_{\wedge}^n(M) \subseteq \sum_{\sigma \in \Sigma_n} \text{im}(\sigma - \text{sgn}(\sigma)) \subseteq \ker(p_{\text{sgn}})$, so that p_{sgn} factorizes through a unique homomorphism $\psi_{\text{sgn}}: \wedge^n(M) \rightarrow T_{\wedge}^n(M)$. We have $\psi_{\text{sgn}} \phi_{\text{sgn}} = n! \cdot \text{id}$ and $\phi_{\text{sgn}} \psi_{\text{sgn}} = n! \cdot \text{id}$.

Proposition 3.1.20. *Assume that $n!$ is invertible in R . Then ϕ_{χ} is an isomorphism and we have $T^n(M) = T_{\text{Sym}}^n(M) \oplus I_{\text{Sym}}^n(M) = T_{\wedge}^n(M) \oplus I_{\wedge}^n(M)$. In particular, we have canonical isomorphisms of R -modules $T_{\text{Sym}}^n(M) \xrightarrow{\sim} \text{Sym}^n(M)$ and $T_{\wedge}^n(M) \xrightarrow{\sim} \wedge^n M$.*

Proof. We may assume $n \geq 2$. Then 2 is invertible in R . It is clear that ϕ_{χ} is an isomorphism. Since $\phi_{\chi} \psi_{\chi} = q_{\chi}(i_{\chi} \psi_{\chi})$ is an isomorphism, where $i_{\chi}: T_{\chi}^n(M) \hookrightarrow T^n(M)$ is the inclusion, we have $T^n(M) = \ker(q_{\chi}) \oplus \text{im}(\psi_{\chi})$. Since ψ_{χ} is an isomorphism, $\text{im}(\psi_{\chi}) = T_{\chi}^n(M)$. \square

Remark 3.1.21. If 2 is invertible in R , then we have an isomorphism $T^2(M) \xrightarrow{\sim} \text{Sym}^2(M) \oplus \wedge^2(M)$ carrying $x \otimes y$ to $(xy, x \wedge y)$.

Remark 3.1.22. The R -submodule $T_{\text{Sym}}(M) \subseteq T(M)$ is not closed under multiplication in general. However, we can equip $T_{\text{Sym}}(M)$ with the structure of a commutative R -algebra by $xy = \sum_{\sigma \in \Sigma_{i+j}/\Sigma_i \times \Sigma_j} \sigma(x \otimes y)$ for $x \in T_{\text{Sym}}^i(M)$ and $y \in T_{\text{Sym}}^j(M)$. The map $\psi: \text{Sym}(M) \rightarrow T_{\text{Sym}}(M)$ is a homomorphism of R -algebras.

3.2 Semisimple rings

Theorem 3.2.1 (Wedderburn–Artin). *Let R be a ring. The following conditions are equivalent:*

- (1) ${}_R R$ is a semisimple module.
- (2) R_R is a semisimple module.
- (3) $R \simeq M_{n_1}(D_1) \times \cdots \times M_{n_r}(D_r)$, where the D_i are division rings.

Definition 3.2.2. A ring satisfying the above conditions is said to be *semisimple*.

Proof. Since transposition provides an isomorphism $M_n(D)^{\text{op}} \simeq M_n(D^{\text{op}})$, it suffices to show (2) \Leftrightarrow (3).

(3) \Rightarrow (2). We have $R_R \simeq (D_1^{n_1})^{\oplus n_1} \oplus \cdots \oplus (D_r^{n_r})^{\oplus n_r}$, where each $D_i^{n_i}$ is a simple right R -module.

(2) \Rightarrow (3). We have $R_R = \bigoplus_{i \in I} \mathfrak{a}_i$, where each $f\mathfrak{a}_i$ is a minimal right ideal of R . There exists a finite subset $J \subseteq I$ such that $1 = \sum_{j \in J} x_j$ for $x_j \in \mathfrak{a}_j$. It follows that $I = J$ is finite. We have $R_R \simeq \bigoplus_{i=1}^r M_i^{\oplus n_i}$, where each M_i are pairwise nonisomorphic simple right R -module. By Schur's lemma $D_i = \text{End}((M_i)_R)$ is a division algebra. We have an isomorphism $\text{End}(R_R) \xrightarrow{\sim} R$ carrying f to $f(1)$, with inverse carrying a to $x \mapsto ax$. Thus $R \simeq \text{End}(R_R) \simeq \bigoplus_{i=1}^r \text{End}((M_i^{\oplus n_i})_R) \simeq \bigoplus_{i=1}^r M_{n_i}(D_i)$. \square

Remark 3.2.3. By the Jordan–Hölder theorem, the pairs (n_i, D_i) are uniquely determined by the isomorphism class of R up to permutation and isomorphism.

Corollary 3.2.4. *A semisimple ring is Noetherian and Artinian.*

Proposition 3.2.5. *Let R be a semisimple ring. Then every left (or right) R -module M is semisimple.*

Proof. Indeed, M is a quotient of a free module $R^{\oplus I}$, which is semisimple. \square

3.3 Simple rings

Definition 3.3.1. A ring R is said to be *simple* if it has exactly two ideals: 0 and R .

For any ring R and any maximal ideal I , R/I is a simple ring.

A commutative ring is simple if and only if it is a field.

Lemma 3.3.2. *Let R be a ring. The ideals of $M_n(R)$ are of the form $M_n(I)$, where I is an ideal of R .*

Proof. Let $J \subseteq M_n(R)$ be an ideal. Let $f: R \rightarrow M_n(R)$ be the embedding carrying r to the matrix with entry r at the upperleft corner and 0 elsewhere. Let $I = f^{-1}(J)$. Then it is easy to see that $J = M_n(I)$. \square

Warning 3.3.3. (1) $R = M_n(D)$, where D is a division ring, is a simple ring.

For $n \geq 2$, neither ${}_R R$ nor R_R is simple.

(2) A simple ring is *not* semisimple in general. Let F be a field, $V = F^{\oplus \mathbb{N}}$, and let $R = \text{End}_F(V)$. Then the subset $I \subseteq R$ consisting of linear operators of finite rank is a maximal ideal (that is, a maximal element of the set of proper ideals), so that $S = R/I$ is a simple ring. Since R does not satisfy IBN, nor does S . It follows that S_S does not have finite length, by the Jordan-Hölder theorem. Thus S is not a semisimple ring.

We make a brief digression on the double centralizer property.

Definition 3.3.4. Let E be a ring. The *centralizer* of a subring $A \subseteq E$ is

$$Z_E(A) := \{z \in E \mid az = za \forall a \in A\}.$$

We have $Z_E(A) \subseteq E$ is a subring and $Z_E(Z_E(A)) \supseteq A$. If equality holds, we say that $A \subseteq E$ satisfies the double centralizer property.

Let M be a left R -module. We apply the above to $E = \text{End}_{\mathbb{Z}}(M)$ and the image A of R in E . We say M is *balanced* if $A \subseteq E$ satisfies the double centralizer property. Note that $Z_E(A) = \text{End}_R(M)$ and $Z_E(Z_E(A)) = \text{End}_{R'}(M)$, where $R' = \text{End}_R(M)$. Thus M is balanced if and only if the canonical homomorphism $R \rightarrow \text{End}_{R'}(M)$ is surjective. We say M is *faithful* if $R \rightarrow \text{End}_{\mathbb{Z}}(M)$ is injective.

Theorem 3.3.5 (Rieffel). *Let R be a simple ring and I a nonzero left ideal of R . Let $R' = \text{End}_R(I)$ and let $R'' = \text{End}_{R'}(I)$. Then the canonical homomorphism $\lambda: R \rightarrow R''$ is an isomorphism.*

In other words, I is balanced and faithful.

Proof. Since $\ker(\lambda)$ is a proper ideal of R , we have $\ker(\lambda) = 0$. Since IR is a nonzero ideal of R , we have $IR = R$ and $\lambda(IR)\lambda(R) = \lambda(R)$. For $h \in R''$ and $a \in I$, $h \cdot \lambda(a) = \lambda(h(a))$. Indeed, for $x \in I$,

$$h(\lambda(a)(x)) = h(ax) = h(\rho_x a) = \rho_x h(a) = h(a)x = \lambda(h(a))(x),$$

where $\rho_x \in R'$ is the right multiplication by x . Thus $\lambda(I)$ is a left ideal of R'' , and

$$R'' = R''\lambda(R) = R''\lambda(I)\lambda(R) = \lambda(I)\lambda(R) = \lambda(R).$$

□

Corollary 3.3.6. *Let R be a simple ring. Then the following conditions are equivalent:*

- (1) R is semisimple;
- (2) R is left Artinian;
- (3) R has a minimal left ideal;
- (4) $R \simeq M_n(D)$ for some $n \geq 1$ and some division ring D .

By a minimal left ideal, we mean a minimal element of the set of nonzero ideals.

Proof. (4) \Rightarrow (1) \Rightarrow (2). We have seen these in the last section.

(2) \Rightarrow (3). Clear.

(3) \Rightarrow (4). Let $I \subseteq R$ be a minimal left ideal. Then $D = \text{End}_R(I)$ is a division ring. By the theorem, $R \simeq \text{End}_D(I)$. Let $J \subseteq \text{End}_D(I)$ be the ideal of D -linear maps $I \rightarrow I$ of finite rank. Then J is a nonzero ideal, so that $J = \text{End}_D(I)$. It follows that $\text{rk}_D(I) = n < \infty$. Then $R \simeq \text{End}_D(D^{\oplus n}) \simeq M_n(D^{\text{op}})$. □

Example 3.3.7. $D \xrightarrow{\sim} \text{End}_{M_n(D^{\text{op}})}(D^n)$.

3.4 Jacobson radicals

Let R be a ring.

Definition 3.4.1. The intersection of the maximal left ideals of R is called the *Jacobson radical* of R and denoted by $\text{rad}(R)$.

Proposition 3.4.2. *For $y \in R$. Then following conditions are equivalent:*

- (1) $y \in \text{rad}(R)$;
- (2) $yM = 0$ for every simple left R -module M ;
- (3) $1 - xy$ has a left inverse for every $x \in R$;
- (4) $1 - xyz$ has an inverse for every $x, z \in R$.

Proof. (2) \Rightarrow (1). Let $I \subseteq R$ be a maximal left ideal. Then R/I is a simple left R -module. By (2), $y(R/I) = 0$. Thus $y \in \text{rad}(R)$.

(3) \Rightarrow (2). If $ym \neq 0$ for $m \in M$, then $M = Rym$ by the simplicity of M . In particular, there exists $x \in R$ such that $m = xym$. In other words, $(1 - xy)m = 0$, which implies $m = 0$.

(4) \Rightarrow (3). Take $z = 1$.

(1) \Rightarrow (3). Otherwise, by Zorn's lemma, $1 - xy$ is contained in a maximal left ideal I of R and $y \in I$, which implies $1 \in I$. Contradiction.

(1) \Rightarrow (4). We have already seen (1) \Rightarrow (2). For every simple left R -module M , $yzM \subseteq yM = 0$. Thus $yz \in \text{rad}(R)$. By (1) \Rightarrow (3), $1 - xyz$ admits a left inverse, say u . Then $u(1 - xyz) = 1$, so that $u = 1 + uxyz$ has a left inverse by (1) \Rightarrow (3). It follows that u and $1 - xyz$ are invertible. \square

For a subset S of a left R -module M , we define the *annihilator* of S to be the left ideal $\text{ann}_R(S) = \{r \in R \mid rs = 0 \forall s \in S\}$. The equivalence (1) \Leftrightarrow (2) above (which is trivial) implies the following.

Corollary 3.4.3. *We have $\text{rad}(R) = \bigcap_M \text{ann}_R(M)$, where M runs through simple left R -modules.*

Note that in (4) remains the same if we replace R by R^{op} . Thus the equivalence (1) \Leftrightarrow (4) above implies the following.

Corollary 3.4.4. *$\text{rad}(R)$ is also the intersection of the maximal right ideals of R . In particular, $\text{rad}(R)$ is an ideal of R .*

Example 3.4.5. (1) Let R be a PID. Then $\text{rad}(R) = 0$. Let $r = \prod_{i=1}^n p_i^{a_i}$, where p_1, \dots, p_n are pairwise nonassociate irreducible elements of R and $a_i \geq 1$. Then $\text{rad}(R/rR) = \prod_{i=1}^n p_i R/rR$.
 (2) Let R be a local ring. Then $\text{rad}(R)$ is the maximal ideal of R . In this case, $R/\text{rad}(R)$ is a division ring.
 (3) Let F be a field, $V = F^{\oplus \mathbb{N}}$, $R = \text{End}_F(V)$. Then $\text{rad}(R) = 0$. Indeed, for every one-dimensional subspace L of V , the endomorphisms of V vanishing on L form a maximal left ideal of R . However, R has a unique maximal ideal, which is nonzero. In particular, $\text{rad}(R)$ is not the intersection of the maximal ideals of R .

Lemma 3.4.6 (Nakayama). *Let M be a finitely-generated left R -module such that $\text{rad}(R)M = M$. Then $M = 0$.*

Proof. Assume that M is nonzero. By the lemma below, there exists a submodule $N \subseteq M$ such that M/N is simple. Then $\text{rad}(R)(M/N) = 0$. It follows that $\text{rad}(R)M \subseteq N$. Contradiction. \square

Lemma 3.4.7. *Let M be a nonzero finitely-generated left R -module. Then M has a simple quotient.*

Proof. Let $M = \sum_{i=1}^n Rm_i$ and $M_k = \sum_{i=1}^k Rm_i$. There exists $k \geq 1$ such that $M = M_k \supsetneq M_{k-1}$. Then $M = M_{k-1} + Rm_k$ and $M/M_{k-1} \simeq R/I$ is cyclic, where I is a proper left ideal. Let J be a maximal ideal containing I . Then the simple module R/J is a quotient of M . \square

Definition 3.4.8. Let $I \subseteq R$ be a left ideal. We say that I is *nil* if every $x \in I$ is nilpotent. We say that I is *nilpotent* if there exists $n \geq 1$ such that $I^n = 0$.

Nilpotent ideals are nil.

Lemma 3.4.9. *Let $I \subseteq R$ be a nil left ideal. Then $I \subseteq \text{rad}(R)$.*

In particular, if R is commutative, then $\text{nil}(R) \subseteq \text{rad}(R)$.

Proof. Let $y \in I$ and $x \in R$. Then $(1 - xy)^{-1} = \sum_{i=0}^{\infty} (xy)^i$. □

Proposition 3.4.10. *Let R be a left Artinian ring. Then $\text{rad}(R)$ is nilpotent. Moreover, it is the largest nil left ideal and the largest nil right ideal.*

Proof. The second assertion follows from the lemma. Let $I = \text{rad}(R)$. We have a descending chain $I \supseteq I^2 \supseteq \dots$. There exists $n \geq 0$ such that $I^m = I^n$ for all $m \geq n$. Assume $I^n \neq 0$. Then there exists a minimal element J_0 in the set of left ideals J such that $I^n J \neq 0$. Let $a \in J_0$ such that $I^n a \neq 0$. Then $I^n(I^n a) = I^n a \neq 0$, so that $I^n a = J_0$ by the minimality of J_0 . In particular, there exists $y \in I^n$ such that $ya = a$. Since $1 - y \in R^\times$, we have $a = 0$. Contradiction. □

Corollary 3.4.11. *Let R be a left Artinian ring. Then every nil left or right ideal is nilpotent.*

3.5 Semiprimitive and semiprimary rings

Definition 3.5.1. A ring R is said to be *semiprimitive* if $\text{rad}(R) = 0$.

For an ideal I of a ring R contained in $\text{rad}(R)$, we have $\text{rad}(R/I) = \text{rad}(R)/I$. In particular, for any ring R , $R/\text{rad}(R)$ is semiprimitive.

Proposition 3.5.2. *A ring R is semiprimitive if and only if there exists a semisimple faithful left R -module M .*

Proof. Assume that there exists a semisimple faithful left R -module M . Then $\text{rad}(R)M = 0$ by the semisimplicity. It follows that $\text{rad}(R) = 0$ by the faithfulness.

For the converse, assume that $\text{rad}(R) = 0$. Let M be the direct sum of all simple quotients of ${}_R R$. Then $\ker(R \rightarrow \text{End}_{\mathbb{Z}}(M)) = \text{rad}(R) = 0$. □

Remark 3.5.3. In a semiprimitive ring R , every minimal left ideal I is a direct summand of ${}_R R$. Indeed, since $\text{rad}(R) = 0$, there exists a maximal left ideal J such that $J \not\supseteq I$. Then $J + I = R$ by the maximality of J and $J \cap I = 0$ by the minimality of I . Thus ${}_R R = I \oplus J$.

Proposition 3.5.4. *A ring R is semisimple if and only if it is semiprimitive and left Artinian.*

Proof. Assume R semisimple. We have seen that R is left Artinian. Write ${}_R R = \bigoplus_{i=1}^n I_i$ with I_i simple. Then for each j , $\bigoplus_{i \neq j} I_i$ is a maximal left ideal of R and their intersection is zero. It follows that $\text{rad}(R) = 0$.

Conversely, assume that R is semiprimitive and left Artinian. Since R is left Artinian, every nonzero left ideal contains a minimal left ideal. To show that R is a semisimple, we may assume $R \neq 0$. Let $J_0 = {}_R R$. Take a minimal left ideal $I_1 \subseteq J_0$. Then $I = I_1 \oplus J_1$. If $J_1 = 0$, we are done. Otherwise, there exists a minimal left ideal

$I_2 \subseteq J_1$. Since I_2 is a direct summand in ${}_R R$, it is a direct summand in any left ideal containing I_2 . In particular, $J_1 = I_2 \oplus J_2$. Continuing in this way, get a descending chain ${}_R R = J_0 \supseteq J_1 \supseteq \dots$ and minimal left ideals I_i such that $I_i \oplus J_i = J_{i-1}$. Since R is left Artinian, the process must stop after a finitely many, say n , steps. Then ${}_R R = \bigoplus_{i=1}^n I_i$. \square

Remark 3.5.5. In the proof each J_i is a cyclic left R -module, hence a principal left ideal. Thus we have in fact proved that R is semisimple if and only if R is semiprimitive and satisfies the descending chain condition for principal left ideals.

Example 3.5.6. \mathbb{Z} is semiprimitive. More generally, a PID with infinitely many maximal ideals is semiprimitive. But a PID is not semisimple unless it is a field.

Definition 3.5.7. We say that a ring R is *semilocal* if $R/\text{rad}(R)$ is left Artinian. We say that R is *semiprimary* if R is semilocal and $\text{rad}(R)$ is nilpotent.

A ring R is semilocal if and only if $R/\text{rad}(R)$ is semisimple.

Example 3.5.8. (1) A local ring is semilocal.
 (2) A left Artinian ring R is semiprimary. Indeed, $R/\text{rad}(R)$ is clearly left Artinian, and $\text{rad}(R)$ is nilpotent by Proposition 3.4.10.

Theorem 3.5.9 (Hopkins–Levitzki). *Let R be a semiprimary ring and M a left R -module. Then M is a Noetherian module if and only if M is an Artinian module.*

Proof. It suffices to show that if M is Noetherian or Artinian, then M has finite length. Let $J = \text{rad}(R)$. We have $J^n = 0$ for some n . Consider the sequence $M = J^0 M \supseteq JM \supseteq \dots \supseteq J^n M = 0$. Let $N_i = J^{i-1} M / J^i M$, which is an R/J -module. Since R/J is a semisimple ring, N_i is a semisimple module. If M is Noetherian or Artinian, then so is each N_i , and it follows that each N_i has finite lengths, which imply that M has finite length. \square

Corollary 3.5.10. *A ring R is left Artinian if and only if R is semiprimary and left Noetherian.*

We summarize some properties of rings as follows.

3.6 Jacobson density theorem

Let R be a ring, M a left R -module, and $R' = \text{End}_R(M)$. We considered the canonical homomorphism $R \rightarrow R'' = \text{End}_{R'}(M)$ in Section 3.3.

Example 3.6.1. Let $R = \mathbb{Z}$, $M = \bigoplus_p \mathbb{Z}/p\mathbb{Z}$, where p runs through prime numbers. Then $R' = R'' \simeq \prod_p \mathbb{Z}/p\mathbb{Z}$. The homomorphism $R \rightarrow R''$ is not surjective. However, for every $f \in R''$ and every finite subset $S \subseteq M$, there exists $r \in R$ such that $rx = fx$ for every $x \in S$.

Definition 3.6.2. We say that R acts *densely* on ${}_R M$, if for every $f \in R'' = \text{End}_{R'}(M)$ and every finite subset $S \subseteq M$, there exists $r \in R$ such that $rx = f(x)$ for all $x \in S$.

Remark 3.6.3. (1) If we equip M with the discrete topology and R'' with the coarsest topology such that the action $R'' \times M \rightarrow M$ is continuous, then R acts densely on ${}_R M$ if and only if the image of $R \rightarrow R''$ is dense.
 (2) If R acts densely on ${}_R M$ and ${}_R M$ is finitely generated, then M is balanced. Indeed, it suffices to take S to be the a generating subset of ${}_R M$.

Theorem 3.6.4 (Jacobson density). *Let M be a semisimple left R -module and $R' = \text{End}_R(M)$. Then R acts densely on ${}_R M$.*

Lemma 3.6.5. *Let M be a semisimple left R -module. Then every R -submodule $N \subseteq M$ is an R'' -submodule.*

Proof. By semisimplicity we have $M = N \oplus P$ as left R -module. Let $e = \text{id}_N \oplus 0_P: M \rightarrow M$. Then $e \in R'$. For every $f \in R''$, $f(N) = f(eM) = ef(M) \subseteq N$. \square

Proof of Theorem 3.6.4. Let $f \in R''$ and $x_1, \dots, x_n \in M$. Let $R'_n = \text{End}_R(M^{\oplus n}) = M_n(R')$. Then $f^{\oplus n} \in \text{End}_{R'_n}(M^{\oplus n})$. Indeed, for $a = (a_{i,j}) \in M_n(R')$ and $m = (m_1, \dots, m_n)^T \in M^{\oplus n}$, we have

$$f^{\oplus n} am = (f(\sum_j a_{i,j} m_j))_i = \sum_j a_{i,j} f(m_j) = a f^{\oplus n} m.$$

By the lemma, $N = R(x_1, \dots, x_n)^T \subseteq M^{\oplus n}$ is stable under $f^{\oplus n}$. Thus, there exists $r \in R$ such that $f^{\oplus n}(x_1, \dots, x_n)^T = r(x_1, \dots, x_n)^T$, that is, $f(x_i) = rx_i$ for all i . \square

Proposition 3.6.6. *Let M be a semisimple left R -module. Then ${}_R M$ is semisimple.*

Proof. Note that every element in M is a finite sum of elements x such that ${}_R Rx$ is simple. It suffices to show that for ${}_R Rx$ simple, ${}_R R'x$ is simple. Let $a \in R'$ such that $ax \neq 0$. It suffices to show that $R'ax = R'x$. Note that a induces an isomorphism $a_0: Rx \xrightarrow{\sim} Rax$. Choose a decomposition $M = Rax \oplus N$ as left R -module and let $b: M \xrightarrow{p} Rax \xrightarrow{a_0^{-1}} Rx \hookrightarrow M$, where p is the projection. Then $ba x = x$, so that $R'ax = R'x$. \square

Corollary 3.6.7. *Let R be a left Artinian ring and M a semisimple left R -module. Then ${}_R M$ is balanced and ${}_R M$ is finitely generated.*

Proof. Since R is left Artinian, the set $\{\text{ann}_R(S)\}$, where S runs through finite subsets of M , admits a minimal element $I = \text{ann}_R(S)$. For every $x \in M$, the minimality of I implies that $\text{ann}_R(S \cup \{x\}) = I \cap \text{ann}_R(x)$ equals I , that is, $I \subseteq \text{ann}_R(x)$. Let $R'S = \sum_{s \in S} R's$. Since ${}_R M$ is semisimple, we have a decomposition

$M = R'S \oplus N$ as left R' -module. Let $e = 0_{R'S} \oplus \text{id}_N \in R''$. For every $x \in N$, by Jacobson density theorem applied to $S \cup \{x\}$, there exists $r \in R$ such that $rS = 0$ but $rx = x$, which implies $r \in I$ and $x = rx = 0$. Therefore, $M = R'S$ is finitely generated. It then follows from Jacobson density theorem applied to S that ${}_R M$ is balanced. \square

The following are examples where the conclusion of the Jacobson density theorem was already known.

Example 3.6.8. Let $R = D$ be a division ring, $M = D^n$. Then $R' = M_n(D^{\text{op}})$. The homomorphism $D \rightarrow \text{End}_{M_n(D^{\text{op}})}(D^n)$ is an isomorphism.

Example 3.6.9. Let R be a semilocal ring. Then $\bar{R} := R/\text{rad}(R)$ is a semisimple ring. Simple R -modules are the same as simple \bar{R} -modules. By the Wedderburn–Artin theorem, there are simple R -modules M_1, \dots, M_r satisfying $M_i \not\cong M_j$ for $i \neq j$, such that $\bar{R} \rightarrow \prod_{i=1}^r \text{End}_{D_i}(M_i)$ is an isomorphism of rings. Here $D_i = \text{End}_R(M_i)$, which is division ring by Schur's lemma. This map composed with $R \rightarrow R/\text{rad}(R)$ can be identified with $R \rightarrow \text{End}_{R'}(M)$, where $M = \bigoplus_{i=1}^r M_i$ and $R' = \text{End}_R(M) = \prod_{i=1}^r D_i$.

We have ${}_R \bar{R} \simeq \bigoplus_{i=1}^r M_i^{\oplus n_i}$, where $n_i = \text{rk}_{D_i}(M_i)$. Every simple R -module is a quotient of ${}_R \bar{R}$ and thus is isomorphic to some M_i by the Jordan–Hölder theorem.

The following is an important special case.

Theorem 3.6.10 (Burnside). *Let F be an algebraically closed field and R a finite-dimensional F -algebra.*

- (1) *For every simple left R -module M , the canonical map $F \rightarrow \text{End}_R(M)$ is an isomorphism.*
- (2) *We have $\bar{R} := R/\text{rad}(R) \xrightarrow{\sim} \prod_{i=1}^r \text{End}_F(M_i)$, where M_1, \dots, M_r is a system of representatives of isomorphism classes of simple R -modules. In particular, $\dim_F \bar{R} = \sum_{i=1}^r (\dim_F M_i)^2$.*

It remains to prove (1).

Let F be a field and R a nonzero F -algebra. Then the structural homomorphism $F \rightarrow R$ is an injection. We regard F as a subfield of R .

Lemma 3.6.11. *Let F be a field and D a finite-dimensional F -algebra without zerodivisors. Then D is a division ring and D is the union of maximal subfields of D containing F . In particular, if F is algebraically closed, then $D = F$.*

An F -algebra that is a division ring is called a *division F -algebra*.

Proof. Let $x \in D$. The kernel of the homomorphism $F[X] \rightarrow D$ carrying P to $P(x)$ is of the form (P) . Since $\dim_F D < \infty$, $P(X) \neq 0$. If $P = QR$, then $Q(x) = 0$ or $R(x) = 0$, so that $P \mid Q$ or $P \mid R$. Thus P is irreducible. Then $F[x] \simeq F[X]/(P)$ is a field extension of F . Thus $D = \bigcup_{x \in D} F[x]$ is a union of subfields of D containing F . Each subfield of D containing F is contained in a maximal subfield. The first assertion follows. For the last assertion, note that every subfield of D containing F is an algebraic extension of F , and hence is F if F is algebraically closed. \square

3.7 Central simple algebras

Any ring A is a $Z(A)$ -algebra.

Remark 3.7.1. Let A be a simple ring. Then $Z(A)$ is a field. Indeed, for nonzero $a \in Z(A)$, $Ra = aR$ is a nonzero ideal of R , and hence equals to R . In other words, a is invertible in R . It follows that $a^{-1} \in Z(A)$, and $a \in Z(A)^\times$.

In the sequel let F be a field.

Definition 3.7.2. Let A be an F -algebra. We say that A is *central* if $Z(A) = F$. We say that A is *central simple* if it is a central F -algebra and a simple ring.

Remark 3.7.3. A finite-dimensional central simple F -algebra is Noetherian and Artinian, and hence isomorphic to $M_n(D)$ for some division ring D and some $n \geq 1$. Then $F \simeq Z(M_n(D)) = Z(D)$ and D is a central division F -algebra.

Example 3.7.4. (1) (Dickson) Let E/F be a finite cyclic extension with Galois group $\langle \sigma \rangle$ of order n . Fix $a \in F^\times$. Let $A = A(E/F, \sigma, a) = E \oplus Ex \oplus \cdots \oplus Ex^{n-1}$ with $x^n = a$ and $xb = \sigma(b)x$ for $b \in E$. We call A the cyclic F -algebra associated to E/F , σ , and a . One can check that A is a central simple F -algebra of dimension n^2 [L2, Theorem 14.6].

(2) Assume that F contains a primitive n -th root of unity ζ and let $a, b \in F^\times$. We define $(a, b)_\zeta$ to be the F -algebra generated by x and y subject to the relations $x^n = a$, $y^n = b$, and $xy = \zeta yx$. One can check that A is a central simple F -algebra of dimension n^2 . In the case where $[F(\sqrt[n]{b}) : F] = n$, we have $(a, b)_\zeta \simeq A(F(\sqrt[n]{b})/F, \sigma, a)$, where σ is given by $\sigma(\sqrt[n]{b}) = \zeta \sqrt[n]{b}$.

(3) Hamilton's quaternion algebra $\mathbb{H} = (-1, -1)_{-1} = \mathbb{R} \oplus \mathbb{R}i \oplus \mathbb{R}j \oplus \mathbb{R}k$ with $i^2 = j^2 = k^2 = ijk = -1$ is a division \mathbb{R} -algebra. Indeed, $(a + bi + cj + dk)(a - bi - cj - dk) = a^2 + b^2 + c^2 + d^2$ for $a, b, c, d \in \mathbb{R}$.

One can show that over a field F of characteristic $\neq 2$, a 4-dimensional central simple F -algebra is isomorphic to some $(a, b)_{-1}$.

We are interested in tensor products of central simple algebras.

Definition 3.7.5. Let A be an F -algebra. We call $A^e := A \otimes_F A^{\text{op}}$ the *enveloping algebra* of A .

If $A \subseteq B$ is an F -subalgebra, we regard B as a left A^e -module by $(a \otimes a')b = aba'$. In particular, A is a left A^e -module. Left A^e -submodules of A are precisely ideals of A .

Lemma 3.7.6. *The homomorphism*

$$\begin{aligned} \text{Hom}_{A^e}(A, B) &\rightarrow Z_B(A) \\ f &\mapsto f(1) \end{aligned}$$

is an isomorphism.

Note that $f(1) \in Z_B(A)$ since $f(a) = af(1) = f(1)a$.

Proof. The inverse carries c to $a \mapsto ca = ac$. \square

In particular, we have $\text{End}_{A^e}(A) \xrightarrow{\sim} Z(A)$ carrying f to $f(1)$.

Lemma 3.7.7. *Let A be a finite-dimensional central F -algebra. Then A is simple if and only if the homomorphism*

$$\begin{aligned} \lambda: A \otimes_F A^{\text{op}} &\rightarrow \text{End}_F(A) \\ a \otimes b &\mapsto (x \mapsto axb) \end{aligned}$$

is surjective. In this case, λ is an isomorphism.

Proof. Suppose A is not simple and $0 \neq I \subsetneq A$ is an ideal, then for all $a, b \in A$, $\lambda(a \otimes b)$ stabilizes I . Thus λ is not surjective.

Conversely, assume that A is simple. Then A is a simple left A^e -module. Moreover, $\text{End}_{A^e}(A) \simeq Z(A) = F$. By Jacobson density theorem, $\lambda: A^e \rightarrow \text{End}_F(A)$ is surjective. Counting dimensions, we see that λ is an isomorphism. \square

Proposition 3.7.8. *Let A be an F -algebra and let E/F be a field extension. Then $Z(A \otimes_F E) \simeq Z(A) \otimes_F E$. In particular, A is a central F -algebra if and only if $A \otimes_F E$ is a central E -algebra. Moreover, if A is finite dimensional, then A is central simple if and only if $A \otimes_F E$ is central simple.*

Proof. The first assertion follows from the fact that $Z(A)$ is the space of solutions of the F -linear equations $xa - ax = 0$, where a runs through an F -linear basis of A . The last assertion follows from Lemma 3.7.7. \square

Example 3.7.9. $\mathbb{H} \otimes_{\mathbb{R}} \mathbb{C} \simeq M_2(\mathbb{C})$.

Let A and C be F -algebras. We regard A as a subalgebra of $A \otimes_F C$ via the homomorphism $A \rightarrow A \otimes_F C$ carrying a to $a \otimes 1$ and we regard C as a subalgebra of $A \otimes_F C$ via the homomorphism $C \rightarrow A \otimes_F C$ carrying c to $1 \otimes c$.

Proposition 3.7.10. *Assume that A is a central F -algebra. Then $Z_{A \otimes_F C}(A) = C$.*

Proof. It is clear that $C \subseteq Z_B(A)$. Let (c_i) be an F -linear basis of C . Then every $b \in B$ can be written uniquely as $b = \sum_i a_i \otimes c_i$, where $a_i \in A$. Assume $b \in Z_B(A)$. For all $a \in A$, $\sum_i aa_i \otimes c_i = ab = ba = \sum_i a_i a \otimes c_i$, which implies $aa_i = a_i a$ for all i . Thus $a_i \in Z(A) = F$ for all i and $b \in C$. \square

In the case where A is simple and finite-dimensional, the proposition admits the following converse.

Theorem 3.7.11. *Let B be an F -algebra. Let $A \subseteq B$ be a finite-dimensional F -subalgebra which is central simple. Let $C = Z_B(A)$. Then the homomorphism $\theta: A \otimes_F C \rightarrow B$ carrying $a \otimes c$ to ac is an isomorphism and we have a bijection*

$$\begin{aligned} \{\text{ideals of } C\} &\leftrightarrow \{\text{ideals of } B\} \\ I &\mapsto AI = \theta(A \otimes_F I) \\ J \cap C &\leftarrow J. \end{aligned}$$

Moreover, $Z(B) = Z(C)$.

Lemma 3.7.12. *Let V and W be F -vector spaces. Let $W_0 \subseteq W$ be an F -vector subspace and let $0 \neq v \in V$. Then the set of $w \in W$ such that $v \otimes w \in V \otimes_F W_0$ is precisely W_0 .*

Proof. We extend v to an F -linear basis (v_i) of V . Every element of $V \otimes_F W$ can be written uniquely as $\sum_i v_i \otimes w_i$ with $w_i \in W$. We conclude by applying the existence to $v \otimes w \in V \otimes_F W_0$ and the uniqueness to $V \otimes_F W$. \square

Lemma 3.7.13. *Let V be an F -vector space and let $E = \text{End}_F(V)$.*

(1) *Let W be an F -vector space. Every left E -submodule of $V \otimes_F W$ has the form $V \otimes_F W_0$ for some F -linear subspace $W_0 \subseteq W$.*

(2) *Let M be a left E -module. The homomorphism of E -modules*

$$\begin{aligned} \theta: V \otimes_F \text{Hom}_E(V, M) &\rightarrow M, \\ a \otimes f &\mapsto f(a) \end{aligned}$$

is an injection. If, moreover, V is finite dimensional, then θ is an isomorphism.

Proof. (1) Let $X \subseteq V \otimes_F W$ be an E -submodule. Let $W_0 \subseteq W$ be the F -vector subspace of w such that $v \otimes w \in X$. Then $V \otimes_F W_0 \subseteq X$. Conversely, let $x \in X$. Choose a basis (v_i) of V and write $x = \sum_i v_i \otimes w_i$. For each j , there exists $\phi_{ij} \in E$ such that $\phi_{i,j}(v_i) = v_j$ and $\phi_{i,j}(v_{i'}) = 0$ for all $i' \neq i$. Then $\phi_{i,j}x \in X$ for all j implies $w_i \in W_0$. Thus $x \in V \otimes_F W_0$.

(2) Let $\ker(\theta) = V \otimes_F W_0$. For each $f \in W_0$, $f(V) = 0$. Thus $\ker(\theta) = 0$. Assume that $n = \dim_F V < \infty$. Then $E \simeq M_n(F)$ is semisimple and every simple left E -module is isomorphic to V . Thus $M = V^{\oplus S}$. The composite $V \otimes_F F^{\oplus S} \rightarrow V \otimes_F \text{Hom}_E(V, V^{\oplus S}) \xrightarrow{\theta} V^{\oplus S}$ is an isomorphism. It follows that θ is a surjection. \square

Proof of Theorem 3.7.11. Via Lemma 3.7.6, θ can be identified with the homomorphism $\theta: A \otimes_F \text{Hom}_{A^e}(A, B) \rightarrow B$ given by $a \otimes f \mapsto f(a)$. By Lemma 3.7.7, $A^e \simeq \text{End}_F(A)$. Thus θ is an isomorphism by Lemma 3.7.13.

By Lemma 3.7.12 and Lemma 3.7.13 (1), the maps are bijections between F -vector subspaces $I \subseteq C$ and A -submodules $J \subseteq B$. Both maps preserve ideals.

We have $Z(B) \subseteq Z_B(A) = C$. Thus $Z(B) \subseteq Z(C)$. Conversely, every $x \in Z(C)$ centralizes both A and C , and hence we have $x \in Z(B)$. \square

Corollary 3.7.14. *Let A be a finite-dimensional central simple F -algebra and let C be an F -algebra. Then C is simple if and only if $A \otimes_F C$ is. Moreover, C is central if and only if $A \otimes_F C$ is.*

Combining this with the Wedderburn–Artin theorem, we obtain the following.

Corollary 3.7.15. *Let A be a finite-dimensional central simple F -algebra and let C be a finite-dimensional semisimple F -algebra. Then $A \otimes_F C$ is a semisimple F -algebra.*

Example 3.7.16. Let A and B be F -algebras. Then Kronecker product gives an isomorphism $M_m(A) \otimes_F M_n(B) \simeq M_{mn}(A \otimes_F B)$ of F -algebras.

Theorem 3.7.17. *Let B be a finite-dimensional central simple F -algebra and let A be a semisimple F -subalgebra.*

- (1) *We have $Z_B(Z_B(A)) = A$.*
- (2) *If A is simple, then $Z_B(A)$ is simple. Moreover, in this case, $\dim_F B = \dim_F A \cdot \dim_F Z_B(A)$.*

The following is a variant of Lemma 3.7.6.

Lemma 3.7.18. *Let A be an F -subalgebra of an F -algebra B . Then we have an isomorphism of F -algebras*

$$\begin{aligned} \text{End}_{A \otimes_F B^{\text{op}}}(B) &\rightarrow Z_B(A) \\ f &\mapsto f(1) \\ (b \mapsto cb) &\leftarrow c. \end{aligned}$$

This is clear. Note that $f(1) \in Z_B(A)$ since $af(1) = f(a) = f(1)a$. Moreover, $b \mapsto cb$ is a homomorphism of left A -modules since $cab = acb$. The map from right to left is clearly a homomorphism of F -algebras.

Proof of Theorem 3.7.17. Let $R = A \otimes_F B^{\text{op}}$, which is semisimple, and let $R' = \text{End}_R(B) \simeq Z_B(A)$.

(1) By Jacobson density theorem, the (injective) homomorphism $R \rightarrow R' = \text{End}_{R'}(B)$ deduced from $\lambda: B \otimes_F B^{\text{op}} \xrightarrow{\sim} \text{End}_F(B)$ is surjective. Let $x \in Z_B(Z_B(A))$. Then the endomorphism $b \mapsto xb$ of B belongs to R' . Thus $x \otimes 1 \in A \otimes_F B^{\text{op}}$, which implies $x \in A$ by Lemma 3.7.12. This proves $Z_B(Z_B(A)) \subseteq A$. The inverse inclusion is obvious.

(2) Assume A simple. Then R is simple. Then $R \simeq M_n(D^{\text{op}})$ for some division F -algebra D and some $n \geq 1$. Let $M = D^{\oplus n}$ be the simple R -module. We have $D \simeq \text{End}_R(M)$. Then ${}_R B \simeq M^{\oplus r}$ for some $r \geq 1$ and $Z_B(A) \simeq R' \simeq M_r(D)$ is simple. Finally,

$$\dim_F B = rn \dim_F D, \quad \dim_F R = n^2 \dim_F D, \quad \dim_F Z_B(A) = r^2 \dim_F D,$$

which implies $(\dim_F B)^2 = \dim_F R \cdot \dim_F Z_B(A) = \dim_F A \cdot \dim_F B \cdot \dim_F Z_B(A)$. \square

Assumption 3.7.19. In the rest of this section, F -algebras are assumed to be finite-dimensional.

Corollary 3.7.20. *Let D be a central division F -algebra and let $K \subseteq D$ be a maximal subfield containing F . Then $Z_D(K) = K$ and $(\dim_F K)^2 = \dim_F D$.*

Proof. Indeed, $Z_D(K)$ is a division K -algebra and $Z_D(K) = K$ by Lemma 3.6.11. \square

It follows from this (or from the fact that $A \otimes_F F^{\text{alg}} \simeq M_d(F^{\text{alg}})$) that the dimension of a central simple F -algebra A is a square d^2 . We call d the *degree* of A .

Example 3.7.21. In \mathbb{H} , $\mathbb{R}[i]$, $\mathbb{R}[j]$, and $\mathbb{R}[k]$ are maximal subfields. All three are isomorphic to \mathbb{C} .

Skolem–Noether Theorem

Let B be an F -algebra. For every $y \in B^\times$, $b \mapsto yby^{-1}$ is an automorphism of the F -algebra B . Such automorphisms are called inner.

Theorem 3.7.22. *Let B be a central simple F -algebra and A a simple F -subalgebra of B . Let $f: A \rightarrow B$ be a homomorphism of F -algebras. Then there exists $y \in B^\times$ such that $f(a) = yay^{-1}$ for all $a \in A$.*

In other words, f extends to an inner automorphism of B .

Proof. Let $R = A \otimes_F B^{\text{op}}$, which is a simple F -algebra by 3.7.14. Since R -modules are semisimple and simple R -modules are also isomorphic, R -modules of the same dimension over F are isomorphic.

We consider two R -module structures on B : $(a \otimes b)x = axb$ and $(a \otimes b)x = f(a)xb$. There exists $g \in \text{Aut}_F(B)$ such that $g(axb) = f(a)g(x)b$ for all $a \in A$, $b, x \in B$. Let $y = g(1)$. Then $f(a)y = g(a) = ya$. \square

Corollary 3.7.23 (Skolem–Noether). *Automorphisms of central simple F -algebras are inner.*

Corollary 3.7.24. *Let B be a central simple F -algebra. If A and A' are simple subalgebras and there exists an F -isomorphism $A \simeq A'$, then A and A' are conjugate to each other. That is, there exists $b \in B^\times$ such that $A' = bAb^{-1}$.*

Proof. This follows from the theorem applied to $A \simeq A' \hookrightarrow B$. \square

Theorem 3.7.25 (Wedderburn’s Little Theorem). *Every finite division ring D is a field.*

Proof. Let $F = Z(D)$, which is a finite field. Then maximal subfields of D containing F are of degree $n = \sqrt{\dim_F D}$ over F , and hence are isomorphic to each other as extensions of F . By Corollary 3.7.24, they are conjugate to each other. Let K be a maximal subfield of D containing F . Then $D^\times = \bigcup_{a \in D^\times} aK^\times a^{-1}$. By the lemma below, this forces $D^\times = K^\times$. Thus $D = K$. \square

Lemma 3.7.26. *Let G be a finite group and $H < G$ a subgroup such that $G = \bigcup_{g \in G} gHg^{-1}$. Then $G = H$.*

Proof. Note that gHg^{-1} depends only on the class of g in G/H . Moreover, $\#(gHg^{-1}) = \#H$. Since $\#G = (G : H)\#H$, the union is disjoint. However, $1 \in gHg^{-1}$ for all g . Thus $(G : H) = 1$. \square

Corollary 3.7.27. *Let D be a division ring of characteristic $p > 0$. Then any finite subgroup G of D^\times is cyclic.*

Proof. Let $R = \mathbb{F}_p[G] \subseteq D$. Then R is a finite ring. For every nonzero $x \in R$, $x^i = x^j$ for some $i \neq j$. Thus R is a finite division ring and hence a finite field. Therefore, $G < R^\times$ is cyclic. \square

Warning 3.7.28. Unlike the case of fields, finite subgroups of the multiplicative group of a division ring of characteristic 0 are not cyclic in general. For example, in \mathbb{H}^\times , $\{\pm 1, \pm i, \pm j, \pm k\}$ is not cyclic.

Theorem 3.7.29 (Frobenius). *Every finite-dimensional division \mathbb{R} -algebra D is isomorphic to \mathbb{R} , \mathbb{C} , or \mathbb{H} .*

Proof. If $[Z(D) : \mathbb{R}] > 1$, then $Z(D) \simeq \mathbb{C}$ and $D \simeq \mathbb{C}$. Assume $Z(D) = \mathbb{R}$ and $\dim_{\mathbb{R}} D = n^2 > 1$. Let K be a maximal subfield of D containing \mathbb{R} . Then $[K : \mathbb{R}] = n > 1$, so that $K \simeq \mathbb{C}$ as field extensions of \mathbb{R} . It follows that $\dim_{\mathbb{R}} D = 4$. Let $i \in K$ be a square root of -1 . By Theorem 3.7.22 applied to the homomorphism $K \rightarrow D$ of \mathbb{R} -algebras carrying i to $-i$, there exists $j \in D^\times$ such that $jij^{-1} = -i$. That is, $iji^{-1} = -j$. Let $K' = \mathbb{R}[j]$. Then $K' \simeq \mathbb{C}$ as field extensions of \mathbb{R} . Consider $\sigma : K' \rightarrow K'$ carrying x to ixi^{-1} . This is a nontrivial element of $\text{Gal}(K'/\mathbb{R})$, and hence corresponds to complex conjugation. Thus $\sigma(j) = -j$ implies $r := -j^2 \in \mathbb{R}_{>0}$. Up to replacing j by j/\sqrt{r} , we may assume $j^2 = -1$. Let $k = ij$. Then $k^2 = ijk = -1$. Thus $\mathbb{R}[i, j, k] \simeq \mathbb{H}$. By dimension count, $\mathbb{R}[i, j, k] = D$. \square

Splitting fields

Definition 3.7.30. Let A be a central simple F -algebra. We say that A is *split* over F if $A \simeq M_n(F)$ for some $n \geq 1$. Let K/F be a field extension. We say that K is a *splitting field* of A , or that A *splits over* K , if $A \otimes_F K$ is a split central simple K -algebra.

Remark 3.7.31. If K is a splitting field of A and B , then it is also a splitting field of $A \otimes_F B$ and A^{op} .

Proposition 3.7.32. *Let $A = M_n(B)$ with B a central simple F -algebra and $n \geq 1$. Then K is a splitting field of A if and only if K is a splitting field of B .*

Proof. If $B \otimes_F K \simeq M_m(K)$, then $M_n(B) \otimes_F K \simeq M_n(B \otimes_F K) \simeq M_{mn}(B)$. Conversely, if $M_n(B) \otimes_F K \simeq M_r(K)$ and if $B \otimes_F K \simeq M_m(E)$ for a division F -algebra E , then $M_{mn}(E) \simeq M_r(K)$ and hence $E \simeq K$ by Remark 3.2.3. \square

Lemma 3.7.33. *Let A be a central simple F -algebra and let $K \subseteq A$ be a subfield containing F . Let $C = Z_A(K)$. Then there exist $m, n \geq 1$ such that $M_m(A \otimes_F K) \simeq M_n(C)$ as K -algebras.*

Note that $A \otimes_F K$ and C are central simple K -algebras. (That C is a central simple K -algebra follows either from Theorem 3.7.17 or the lemma.)

Proof. Let $A_K := A \otimes_F K$. We have $A_K^{\text{op}} \simeq K \otimes_F A^{\text{op}}$. By Lemma 3.7.18, $\text{End}_{A_K^{\text{op}}}(A) \simeq C$. We have $A_K \simeq M_n(D)$, for a division K -algebra D . Let M be the unique simple right A_K -module. Then $\text{End}_{A_K^{\text{op}}}(M) \simeq D$. We have $A_{A_K} \simeq M_{A_K}^{\oplus m}$. It follows that $C \simeq M_m(D)$. \square

Proposition 3.7.34. *Let D be a central division F -algebra. Then every maximal subfield K of D containing F is a splitting field of D .*

Proof. By Corollary 3.7.20, $Z_D(K) = K$. Thus, by the lemma, $M_m(D \otimes_F K) \simeq M_n(K)$ as K -algebras for some $m, n \geq 1$. It follows then from Remark 3.2.3 that $D \otimes_F K \simeq M_r(K)$ for some $r \geq 1$. \square

The maximal subfield K of D containing F are minimal splitting fields of D by the following.

Proposition 3.7.35. *Let D be a central division F -algebra of degree d . Let K be a splitting field of D with K/F finite. Then $d \mid [K : F]$.*

Proof. We have $D \otimes_F K \simeq M_d(K)$, which admits a simple module M with $\dim_K M = d$. Since M is a left D -module, $d^2 \mid d[K : F]$ by counting F -dimensions. \square

Theorem 3.7.36. *Every central division F -algebra D contains a separable extension K of F that is maximal among subfields of D .*

Warning 3.7.37. Subfields of a central division F -algebra containing F are *not* always separable. There are examples of central division F -algebras containing purely inseparable extensions of F .

Proof of Theorem 3.7.36. Let K be a maximal separable subfield of D containing F . We need to show that K is a maximal subfield. Let $C = Z_D(K)$, which is a central division K -algebra. If K is not maximal, then $C \neq K$. The following lemma then contradicts the maximality of K . \square

Lemma 3.7.38. *Let D be a central division F -algebra with $D \neq F$. Then D contains a separable extension $K \supsetneq F$.*

Proof. (Artin) Assume the contrary. Then F is not a perfect field and $\text{char}(F) = p > 0$. For every $x \in D$, $F[x]/F$ is a purely inseparable extension, so that $x^{p^k} \in F$, where $p^k = [F[x] : F] \mid d = \sqrt{\dim_F D}$. Let q be the highest power of p dividing d . Then $x^q \in F$ for all $x \in D$. Choose an F -linear basis $1 = x_1, \dots, x_{d^2}$ of D . There are polynomials $f_i \in F[X_1, \dots, X_{d^2}]$ such that $(\sum_i a_i x_i)^q = \sum_i f_i(a_1, \dots, a_{d^2}) x_i$ for all $a_1, \dots, a_{d^2} \in F$. Thus $f_i(a_1, \dots, a_{d^2}) = 0$ for all $i \geq 2$ and $a_1, \dots, a_{d^2} \in F$. It follows from the lemma below that $f_i = 0$ for all $i \geq 2$. It follows that for every field extension K/F and every $y \in D \otimes_F K$, we have $y^q \in K$. Take K to be a splitting field of F and take y to correspond to $\text{diag}(1, 0, \dots, 0) \in M_d(K)$ for example, we get a contradiction. \square

Lemma 3.7.39. *Let F be an infinite field and let $f \in F[X_1, \dots, X_n]$ such that $f(a_1, \dots, a_n) = 0$ for all $a_1, \dots, a_n \in F$. Then $f = 0$.*

Proof. We proceed by induction on n . The case $n = 0$ is trivial. Let $n \geq 1$. By induction hypothesis, $f(X_1, \dots, X_{n-1}, a) = 0$ for all $a \in F$. Let $f(X_1, \dots, X_n) = \sum_{i_1, \dots, i_n \geq 0} c_{i_1, \dots, i_n} X_1^{i_1} \cdots X_n^{i_n}$, where $c_{i_1, \dots, i_n} \in F$. Fix i_1, \dots, i_{n-1} and let $c_j = c_{i_1, \dots, i_{n-1}, j}$. Then a is a root of the polynomial $\sum_{j \geq 0} c_j X^j$ for all $a \in F$. Since F is infinite, $c_j = 0$ for all j . \square

Corollary 3.7.40. *Every central simple F -algebra splits over a finite separable extension of F .*

Brauer groups

Definition 3.7.41. We say that central simple F -algebras A and B are *similar*, written $A \sim B$, if there exist $m, n \geq 1$ such that $M_m(A) \simeq M_n(B)$ as F -algebras. We let Br_F denote the set of similarity classes of central simple F -algebras. We write $[A]$ for the class of A .

Note that if $A \sim A'$ and $B \sim B'$, then $A \otimes_F B \sim A' \otimes_F B'$. Thus tensor product induces a binary operation on Br_F , which is commutative (since $A \otimes_F B \simeq B \otimes_F A$) and associative, with $[F]$ being the identity element. Moreover, $A \otimes_F A^{\text{op}} \simeq F$, so that $[A^{\text{op}}]$ is an inverse of $[A]$. Thus Br_F is an abelian group, called the *Brauer group* of F .

Note that Br_F is also the set of isomorphism classes of central division F -algebras.

- Example 3.7.42.** (1) If F is a separably closed field, then Br_F is trivial.
 (2) If F is a finite field, then Br_F is trivial by Wedderburn's little theorem.
 (3) If $F = k(X)$ for an algebraically closed field k , then Br_F is trivial by a theorem of Tsen.
 (4) $\text{Br}_{\mathbb{R}} = \{[\mathbb{R}], [\mathbb{H}]\} \simeq \mathbb{Z}/2\mathbb{Z}$ by Frobenius' theorem.
 (5) $\text{Br}_{\mathbb{Q}_p} \simeq \mathbb{Q}/\mathbb{Z}$. This fact is crucial in local class field theory.

Algebraically closed fields and examples (2) and (3) are special cases of C_1 -fields (also called quasi algebraically closed fields), which all have trivial Brauer groups.

For a field extension K/F , we have a homomorphism $\text{Br}_F \rightarrow \text{Br}_K$ given by $[A] \mapsto [A \otimes_F K]$. We let $\text{Br}(K/F)$ denote the kernel. We have $\text{Br}_F = \bigcup_K \text{Br}(K/F)$, where K runs through finite Galois extensions of F .

Remark 3.7.43. Assume that F contains a primitive n -th root of unity ζ . Then $(a, b) \mapsto (a, b)_{\zeta}$ (Example 3.7.4 (2)) induces a biadditive map $F^{\times}/F^{\times n} \times F^{\times}/F^{\times n} \rightarrow \text{Br}_F$, called the Galois symbol (or norm residue symbol). By a theorem of Merkurjev–Suslin (1982), the image of the Galois symbol generates $\text{Br}_F[n]$. (For an abelian group, $A[n] := \ker(A \xrightarrow{\times n} A)$ denotes the n -torsion of A .)

3.8 Galois descent

Let K/F be a Galois field extension with Galois group G . Given a K -vector space W , an action of G on the additive group W is called a Galois action if the following conditions are satisfied:

- (1) $\sigma(ax) = \sigma(a)\sigma(x)$ for all $\sigma \in G$, $a \in K$, and $x \in W$;
- (2) $W = \bigcup_H W^H$, where H runs through open subgroups of G .

Note that (1) implies that the action is F -linear. Moreover, (2) is automatic if K/F is finite. We let $\mathbf{Vect}_{K,G}$ denote the category whose objects are K -vector spaces with Galois actions and whose morphisms are G -equivariant K -linear maps. The G -equivariance of a map f means $f \circ \sigma = \sigma \circ f$ for all $\sigma \in G$.

For any F -vector space V , $V \otimes_F K$ is equipped with the obvious Galois action. We have $(V \otimes_F K)^G \simeq V \otimes_F K^G \simeq V$.

Theorem 3.8.1. *The functor $\mathbf{Vect}_F \rightarrow \mathbf{Vect}_{K,G}$ given by $V \mapsto V \otimes_F K$ is an equivalence of categories. A quasi-inverse is given by $W \mapsto W^G$.*

Proof. We have already seen the isomorphism $(V \otimes_F K)^G \simeq V$, natural in V . Let W be an object of $\mathbf{Vect}_{K,G}$. It suffices to show that the natural morphism $\phi: W^G \otimes_F K \rightarrow W$ in $\mathbf{Vect}_{K,G}$ is an isomorphism. For this, it suffices to show that ϕ is a bijection.

Let $w \in W$. Then $w \in W^H$ for some open subgroup H . We may assume that H is a normal subgroup of G . Let $E = K^H$ and $G/H = \text{Gal}(K/E) = \{1 = \sigma_1, \dots, \sigma_n\}$. Let a_1, \dots, a_n be an F -linear basis of E . By the linear independence of characters (Lemma 1.13.6), $(\sigma_j(a_i))_{i,j}$ is an invertible matrix. Thus there exists $b_1, \dots, b_n \in K^n$ such that $\sum_i b_i \sigma_j(a_i) = \delta_{1,j}$ (Kronecker delta). Then

$$w = \sum_j \delta_{1,j} \sigma_j(w) = \sum_i b_i \sum_j \sigma_j(a_i w).$$

Note that $\sum_j \sigma_j(a_i w) \in (W^H)^{G/H} = W^G$. Thus w belongs to the image of ϕ . This proves the surjectivity of ϕ .

Applying this to the K -vector space $W_0 = \ker(\phi)$, we get a surjection $W_0^G \otimes_F K \rightarrow W_0$. Since $W_0^G = 0$, we have $W_0 = 0$. This proves the injectivity of ϕ .

(One can also prove the injectivity of ϕ directly. Let (v_i) be an F -linear basis of W^G . Let $w = \sum_i a_i v_i \in \ker(\phi)$, $a_i \in K$ be a nonzero element with the least number of i such that $a_i \neq 0$. We may assume that $a_{i_1} = 1$. Note that $W^G \cap \ker(\phi) = 0$. Thus there exists $a_{i_2} \notin F$. There exists $\sigma \in G$ such that $\sigma a_{i_2} \neq a_{i_2}$. Then $\sigma(w) - w \in \ker(\phi)$ has a shorter expression in the basis (v_i) . Contradiction. This proves the injectivity of ϕ . \square)

Example 3.8.2. Let E/F be a finite separable field extension and let K/F be a Galois extension containing E . The image of E under the above functor can be described as follows: we have an isomorphism $E \otimes_F K \xrightarrow{\sim} \prod_{\sigma} K$ in $\mathbf{Vect}_{K,G}$ carrying $a \otimes 1$ to $(\sigma(a))_{\sigma}$. Here σ runs through F -embedding $E \rightarrow K$, and $G = \text{Gal}(K/F)$ acts on the product by $\tau(b_{\sigma}) = (\tau b_{\tau^{-1}\sigma})_{\sigma}$. The G -equivariance is clear. To see that the map is an isomorphism, note that, by the primitive element theorem, $E = F(x) \simeq F[X]/(P(X))$, where $P(X) = \prod_{\sigma}(X - \sigma x)$.

Central simple algebras and Galois cohomology

Let K/F be a finite Galois field extension with group G and let A be a central simple F -algebra of degree n that splits over K . Choose an isomorphism of K -algebras $f: A \otimes_F K \rightarrow M_n(K)$. This is not G -equivariant in general: if it is, then $A \simeq M_n(k)$. Let $GL_n(K) = M_n(K)^{\times}$. The adjoint action $\text{Ad}(g): b \mapsto gbg^{-1}$ of $GL_n(K)$ on $M_n(K)$ factors through a faithful action of $\text{PGL}_n(K) := GL_n(K)/K^{\times}$. By the Skolem–Noether theorem, for each $\sigma \in G$, there exists a unique $c_{\sigma} \in \text{PGL}_n(K)$ such that $\text{Ad}(c_{\sigma}) \circ \sigma \circ f = f \circ \sigma$. For $\sigma, \tau \in G$, we have $c_{\sigma\tau} = c_{\sigma}\sigma(c_{\tau})$. This leads to the following nonabelian generalization of the first group cohomology.

Definition 3.8.3. Let G be a group and let H be a group equipped with an action of G . A map $c: G \rightarrow H$ (written $\sigma \mapsto c_{\sigma}$) is called a *crossed homomorphism* if $c_{\sigma\tau} = c_{\sigma}\sigma(c_{\tau})$ for all $\sigma, \tau \in G$. We let $Z^1(G, H)$ denote the set of crossed homomorphisms $G \rightarrow H$. Note that H acts on this set by $(hc)_{\sigma} = hc_{\sigma}\sigma(h^{-1})$ for $h \in H$, $\sigma \in G$. We let $H^1(G, H)$ denote the set of orbits of this action. This is a pointed set, with the

orbit of $\sigma \mapsto e_H$ being the distinguished element. (Crossed homomorphisms in this orbit are of the form $\sigma \mapsto h\sigma(h^{-1})$ and are called *principal*.)

Theorem 3.8.4. *Let K/F be a finite Galois field extension with group G and let $\text{CSA}_n(K/F)$ be the isomorphism classes of central simple F -algebras of degree n that splits over K . The above construction gives an bijection $\Phi_n: \text{CSA}_n(K/F) \xrightarrow{\sim} H^1(G, \text{PGL}_n(K))$, carrying the class of $M_n(F)$ to the distinguished element of H^1 .*

The inverse of the map is given as follows. Given a crossed homomorphism $c: G \rightarrow \text{PGL}_n(K)$, one applies Galois descent to $M_n(K)$ equipped with the Galois action given by $\sigma \mapsto \text{Ad}(c_\sigma) \circ \sigma$ and get the central simple F -algebra

$$A = \{b \in M_n(K) \mid \text{Ad}(c_\sigma)(\sigma(b)) = b, \forall \sigma \in G\}.$$

The details are left to the reader.

Let H be a group equipped with an action of a group G and let H' be a normal subgroup of H stable under the action of G . Let $H'' = H/H'$. Let $c: G \rightarrow H''$ be a crossed homomorphism. Choose a lifting of c to a map $\tilde{c}: G \rightarrow H$. The map

$$\begin{aligned} G^2 &\rightarrow H' \\ (\sigma, \tau) &\mapsto \sigma(\tilde{c}_\tau)\tilde{c}_{\sigma\tau}^{-1}\tilde{c}_\sigma \end{aligned}$$

measures the failure of c be a crossed homomorphism. Assume that $H' < Z(H)$. Then the map is a 2-cocycle in the following sense.

Definition 3.8.5. Let M be an abelian group equipped with an action of G . A map $f: G^2 \rightarrow M$ is called a *2-cocycle* (or *factor system*) if

$$\rho f(\sigma, \tau) - f(\rho\sigma, \tau) + f(\rho, \sigma\tau) + f(\rho, \sigma) = 0$$

for all $\rho, \sigma, \tau \in G$. A *2-coboundary* is a cocycle given by $(\sigma, \tau) \mapsto \sigma(c_\tau) - c_{\sigma\tau} + c_\sigma$ for some map $c: G \rightarrow M$. We define the second cohomology group of G with coefficient in M by $H^2(G, M) := Z^2(G, M)/B^2(G, M)$, where $Z^2(G, M)$ and $B^2(G, M)$ denote the abelian groups of 2-cocycles and 2-coboundaries, respectively.

The above construction gives rise to a homomorphism $\delta: H^1(G, H'') \rightarrow H^2(G, H')$. Moreover, $\delta^{-1}(0)$ is the image of $H^1(G, H) \rightarrow H^1(G, H'')$.

For K/F finite Galois of group G , we have $\delta_n: H^1(G, \text{PGL}_n(K)) \rightarrow H^2(G, K^\times)$. (In fact, $H^1(G, \text{GL}_n(K))$ is trivial and δ_n is an injection.) The map $\text{CSA}_n(K/F) \rightarrow \text{Br}(K/F)$ carrying the class of A to $[A]$ is clearly an injection. Moreover, $\text{Br}(K/F)$ is the union of the images of $\text{CSA}_n(K/F)$. It follows from the constructions that the maps $\delta_n \circ \Phi_n$ induce a map $\text{Br}(K/F) \rightarrow H^2(G, K^\times)$, which is a group homomorphism.

Theorem 3.8.6. *The group homomorphism $\text{Br}(K/F) \rightarrow H^2(G, K^\times)$ is an isomorphism.*

Remark 3.8.7. Let $\alpha \in \text{Br}_F$. The order of α is called the period of α and denoted $\text{per}(\alpha)$. The degree of a central division F -algebra in the class α is called the (*Schur*) *index* of α and denoted $\text{ind}(\alpha)$. Using the cohomological interpretation, one can show that $\text{per}(\alpha) \mid \text{ind}(\alpha)$ and they have the same prime factors.

We refer to [GS] for a proof of the theorem and a more complete exposition on finite-dimensional central simple algebras.

Chapter 4

Representations of finite groups

4.1 Group representations and modules

Let F be a field and let G be a group.

Definition 4.1.1. A (linear) *representation* of G over F is a pair (V, ρ) , where V is an F -vector space and $\rho: G \rightarrow \text{Aut}_F(V)$ is a group homomorphism. A morphism (or intertwining operator) from one representation (ρ, V) to another (ρ', V') is an F -linear map $f: V \rightarrow V'$ such that the diagram

$$\begin{array}{ccc} V & \xrightarrow{f} & V' \\ \rho(g) \downarrow & & \downarrow \rho'(g) \\ V & \xrightarrow{f} & V' \end{array}$$

commutes.

We will often abbreviate (V, ρ) to V or ρ . Representations of G over F form a category $\mathbf{Rep}_F(G)$.

Our focus is on finite-dimensional representations. If V is one-dimensional, we have a canonical isomorphism $F^\times \simeq \text{Aut}_F(V)$, and ρ is given by a homomorphism $G \rightarrow F^\times$. If V is n -dimensional, choosing a basis $F^{\oplus n} \simeq V$ induces $\text{Aut}_F(V) \simeq \text{GL}_n(F)$, under which ρ becomes a homomorphism $G \rightarrow \text{GL}_n(F)$.

Example 4.1.2. (1) *The trivial representation* of G is F equipped with the trivial action.

(2) Let X be a set equipped with an action of G and let $V = F^{\oplus X}$ be the free F -vector space with basis X . The action of G on X induces a representation of G on V , called a *permutation representation*. In the case where G acts on $X = G$ by left translation, this is called the *regular representation*.

Definition 4.1.3. The *group F -algebra* of G , $F[G]$, is the free F -vector space with basis G , and with multiplication extending the multiplication on G . The identity element is $1 \in G$.

Example 4.1.4. If $G = \langle g \rangle$ is a cyclic group of order n , we have

$$F[G] \xrightarrow{\sim} F[X]/(X^n - 1)$$

carrying g to the image X .

The group algebra is characterized by the following universal property. For every F -algebra, the inclusion $G \rightarrow F[G]$ induces a bijection

$$\mathrm{Hom}_{\mathbf{Alg}_F}(F[G], A) \xrightarrow{\sim} \mathrm{Hom}_{\mathbf{Grp}}(G, A^\times).$$

Indeed, every homomorphism $\rho: G \rightarrow A^\times$ extends uniquely to a homomorphism $F[G] \rightarrow A$ of F -algebras by linearity.

Applying the bijection to $A = \mathrm{End}_F(V)$, we get $\mathrm{Hom}_{\mathbf{Alg}_F}(F[G], \mathrm{End}_F(V)) \xrightarrow{\sim} \mathrm{Hom}_{\mathbf{Grp}}(G, \mathrm{Aut}_F(V))$. Thus an F -linear representation of G on V is the same as a (left) $F[G]$ -module structure on V . Moreover, morphisms of representations are the same as morphisms of $F[G]$ -modules. Thus, we have an isomorphism of categories $F[G]\text{-Mod} \simeq \mathbf{Rep}_F(G)$.

The regular representation corresponds to the regular $F[G]$ -module.

A *subrepresentation* is a $F[G]$ -submodule. A *quotient representation* is a quotient $F[G]$ -module. We say that a representation is *irreducible* if the corresponding $F[G]$ -module is simple. They appear as quotients of the regular representation. Schur's lemma applies: $\mathrm{End}_{F[G]}(V)$ is a division F -algebra for V irreducible. The Jordan–Hölder theorem applies to finite-dimensional representations. If G is a finite group, there are only finitely many isomorphism classes of irreducible representations: they are the Jordan–Hölder factors of the regular representation. The Wedderburn–Artin theorem, in the form of Example 3.6.9, is a powerful tool for studying them.

Direct sums of representations correspond to direct sums of $F[G]$ -modules. We say that a representation is *semisimple* (or *completely reducible*) if the corresponding $F[G]$ -module is semisimple. We say that a representation is *indecomposable* if the $F[G]$ -module is. The Krull–Schmidt–Akizuki theorem applies to finite-dimensional representations: a finite-dimensional representation is a direct sum of indecomposable representations and the indecomposable factors are unique up to permutation and isomorphism (Corollary 2.6.12).

We have the following constructions.

Field extension Let (V, ρ) be a representation of G over F and E/F a field extension. Then $E \otimes_F V$, with G acting trivially on E and by ρ on V , is a representation of G over E . In terms of modules, $E \otimes_F V$ is a module over $E \otimes_F F[G] \simeq E[G]$.

Pullback Let $\phi: H \rightarrow G$ be a group homomorphism and (V, ρ) be a representation of G over F . Then $(V, \rho \circ \phi)$ is a representation of H over F . In terms of modules, this corresponds to restriction of scalars via the homomorphism of F -algebras $F[\phi]: F[H] \rightarrow F[G]$. We ϕ is an inclusion (resp. quotient map), the pullback is called the *restriction* (resp. *inflation*) from G to H .

Subspace of invariants Let (V, ρ) be a representation of G over F . Then $V^G = \{v \in V \mid \rho(g)v = v, \forall g \in G\}$ is an F -vector subspace. We have $V^G = \mathrm{Hom}_{F[G]}(F, V)$, where F denotes the trivial representation of G . This is a kind of pushforward via $G \rightarrow 1$, which will be studied in more generality later.

The constructions below use the following isomorphism of F -algebras

$$\begin{aligned} F[G_1] \otimes_F F[G_2] &\xrightarrow{\sim} F[G_1 \times G_2] \\ g_1 \otimes g_2 &\mapsto (g_1, g_2). \end{aligned}$$

External tensor product Let (V_i, ρ_i) be a representation of G_i over F , $i = 1, 2$.

Then $(V_1 \otimes_F V_2, \rho_1 \boxtimes_F \rho_2)$ is a representation of $G_1 \times G_2$ over F , where $(\rho_1 \boxtimes \rho_2)(g_1, g_2) = \rho_1(g_1) \otimes \rho_2(g_2)$. In terms of modules, $V_1 \otimes_F V_2$ is a module over $F[G_1] \otimes_F F[G_2] \simeq F[G_1 \times G_2]$.

Tensor product Let (V_i, ρ_i) be a representation of G over F , $i = 1, 2$. Then

$(V_1 \otimes_F V_2, \rho_1 \otimes \rho_2)$, obtained from $\rho_1 \boxtimes \rho_2$ by restriction via the diagonal $G \rightarrow G \times G$, is a representation of G over V . More explicitly, $(\rho_1 \otimes \rho_2)(g) = \rho_1(g) \otimes \rho_2(g)$. In terms of modules, this corresponds to restriction of scalars via the homomorphism $F[G] \rightarrow F[G \times G] \simeq F[G] \otimes_F F[G]$ given by $g \mapsto g \otimes g$. This is not to be confused with tensor product over the ring $F[G]$.

The following construction uses the isomorphism $G \xrightarrow{\sim} G^{\text{op}}$ given by $g \mapsto g^{-1}$, which induces an isomorphism $F[G] \simeq F[G^{\text{op}}] \simeq F[G]^{\text{op}}$.

Hom-space Let (V, ρ) and (V', ρ') be representations of G and G' over F , $i = 1, 2$.

Then $\text{Hom}_F(V, V')$ is a representation of $G \times G'$: $(g, g') \in G \times G'$ acts by $f \mapsto \rho'(g') \circ f \circ \rho(g)^{-1}$. In terms of modules, $\text{Hom}_F(V, V')$ is a module over $F[G]^{\text{op}} \otimes_F F[G'] \simeq F[G \times G']$.

- In the case where $G' = 1$ and $V' = F$, $\text{Hom}_F(V_1, F)$ is a representation of G over F , called the *dual* or *contragredient* of (V, ρ) and denotes $(\check{V}, \check{\rho})$.
- In the case $G = G'$, we can restrict further restrict via the diagonal $G \rightarrow G \times G$ and regard $\text{Hom}_F(V, V')$ as a representation of G : $g \in G$ acts by $\rho'(g) \circ f \circ \rho(g)^{-1}$. We have $\text{Hom}_{F[G]}(V, V') = \text{Hom}_F(V, V')^G$.

Remark 4.1.5. Except for the isomorphism $G \simeq G^{\text{op}}$ and the last bullet point, all of the above apply to representations of monoids modulo suitable changes. The contragredient of a representation of a monoid G is a representation of G^{op} . Moreover, some of the above also holds with F replaced by a commutative ring. (In fact, we have already encountered representations over \mathbb{Z} in the definition of group cohomology.)

Theorem 4.1.6 (Maschke). *Let G be a finite group. Then $F[G]$ is semisimple if and only if $\text{char}(F) \nmid \#G$.*

Proof. Assume $\text{char}(F) \nmid \#G$. Let V be an $F[G]$ -module and W an $F[G]$ -submodule. We have $V = W \oplus W'$ for some F -vector subspace. Let $e: V \rightarrow W \hookrightarrow V$ be the idempotent and let $e' = \frac{1}{\#G} \sum_{g \in G} g \circ \pi \circ g^{-1}$. Then $e' \in \text{End}_{F[G]}(V)$, $e'|_W = \text{id}_W$, and $\text{im}(e') = W$. Thus $V = W \oplus \ker(e')$ as $F[G]$ -modules. Therefore, $F[G]$ is semisimple.

Conversely, assume $\text{char}(F) \mid \#G$. Let $s = \sum_{g \in G} g$. We have $gs = sg = s$ for all $g \in G$, so that $s \in Z(F[G])$ and $s^2 = \sum_{g \in G} gs = \#G \cdot s = 0$. Thus Fs is a nilpotent ideal of $F[G]$, and $\text{rad}(F[G]) \supseteq Fs \neq 0$. \square

The study of representations of finite groups can be divided into

- *Ordinary representation theory* for the case $\text{char}(F) \nmid \#G$; and
- *Modular representation theory* for the case $\text{char}(F) \mid \#G$.

We will focus on the ordinary case and refer the reader to [S2, Part III] and [CR, Chapter XII] for the modular case, which is more involved.

4.2 Absolutely simple modules

Let A be an F -algebra. For a field extension E/F , we write $A_E := A \otimes_F E$. For an A -module M , we write $M_E := M \otimes_F E$, which is an A_E -module.

Remark 4.2.1. If M_E is a simple A_E -module, then M is a simple A -module. In fact, if $0 \neq N \subsetneq M$ is an A -submodule, then N_E can be identified with a nonzero proper A_E -submodule of M_E .

Definition 4.2.2. We say that M is an *absolutely simple* A -module if M_E is a simple A_E -module for every field extension E/F . In the case where $A = F[G]$, we say that the corresponding representation is *absolutely irreducible*.

Theorem 4.2.3. *Let A be an F -algebra and M an A -module with $\dim_F M < \infty$. Then the following conditions are equivalent:*

- (1) M is absolutely simple;
- (2) $M_{\bar{F}}$ is simple for an algebraic closure \bar{F} of F ;
- (3) M_E is simple for every finite field extension E/F ;
- (4) M is semisimple and $\text{End}_A(M) = F$;
- (5) The homomorphism $A \rightarrow \text{End}_F(M)$ is surjective.

Proof. (1) \Rightarrow (2). Trivial.

(2) \Rightarrow (3). This follows from Remark 4.2.1.

(3) \Rightarrow (4). Let $\phi \in \text{End}_A(M)$. Choose an eigenvalue λ of ϕ as an F -linear endomorphism and let $E = F(\lambda)$. Let $\phi_E := \phi \otimes \text{id}_E \in \text{End}_{A_E}(M_E) = D$. Since M_E is simple, D is a division ring by Schur's lemma. Since $\phi_E - \lambda$ is not invertible, we have $\phi_E = \lambda$ is a scalar. Thus ϕ is a scalar.

(4) \Rightarrow (5). This follows from the Jacobson density theorem.

(5) \Rightarrow (1). For every field extension, $A_E \rightarrow \text{End}_E(M_E)$ is surjective. The simplicity of M_E follows. \square

Corollary 4.2.4. *Let A be a commutative F -algebra and let M be an absolutely simple A -module with $\dim_F M < \infty$. Then $\dim_F M = 1$.*

In particular, any absolutely irreducible finite-dimensional representation of a commutative group is one-dimensional.

Proof. By (5), $\text{End}_F(M)$ is commutative, which implies $\dim_F M \leq 1$. \square

Corollary 4.2.5. *Let A and B be F -algebras. Let M be an absolutely simple A -module, N an absolutely simple B -module, with $\dim_F M < \infty$, $\dim_F N < \infty$. Then $M \otimes_F N$ is an absolutely simple $A \otimes_F B$ -module.*

We leave it to the reader to state the corresponding result for group representations.

Proof. Indeed, the surjectivity of $A \rightarrow \text{End}_F(M)$ and $B \rightarrow \text{End}_F(N)$ implies the surjectivity of $A \otimes_F B \rightarrow \text{End}_F(M) \otimes_F \text{End}_F(N) \simeq \text{End}_F(M \otimes_F N)$. \square

Proposition 4.2.6. *Let A be a finite-dimensional F -algebra, E/F a field extension, N a simple A_E -module. Then there exists a simple A -module M such that N is a Jordan–Hölder factor of M_E .*

Proof. Choose a composition series $0 = P_0 \subseteq \cdots \subseteq P_n = {}_A A$ with each $M_i := P_i/P_{i-1}$ a simple A -module. Then $((P_i)_E)$ is a filtration of ${}_{A_E}(A_E)$. By Schreier's refinement theorem, this can be refined into a composition series of ${}_{A_E}(A_E)$. Since N is a Jordan–Hölder factor of ${}_{A_E}(A_E)$, it appears as a Jordan–Hölder factor of some $(M_i)_E$. \square

Definition 4.2.7. We say that a finite-dimensional F -algebra A splits if every simple left A -module is absolutely simple. For a field extension E/F , we say that A splits over E if the E -algebra A_E splits. (In the case where $A = F[G]$, we say that G splits over E .)

Proposition 4.2.8. *Let A be a finite-dimensional F -algebra.*

- (1) *A splits if and only if $A/\text{rad}(A) \simeq \prod_{i=1}^r M_{n_i}(F)$ for integers $r \geq 0$, $n_i \geq 1$.*
- (2) *If A splits, then A splits over every field extension E/F .*
- (3) *If A splits over an algebraic extension K/F , then A splits over $E \subseteq K$ finite over F . In particular, any finite-dimensional A -algebra splits over a finite extension of F .*

It follows from (1) that the above definition is compatible with the definition of split central simple algebras. Moreover, a finite-dimensional simple F -algebra is split if and only if it is isomorphic to $M_n(F)$ for some $n \geq 1$.

Proof. (1) This follows from the Wedderburn–Artin theorem in the form of Example 3.6.9, together with condition (4) of Theorem 4.2.3.

(2) Let N be a simple A_E -module. By Proposition 4.2.6, there exists a simple A -module M such that N is a Jordan–Hölder factor of M_E . Since M is absolutely simple, M_E is simple and $N \simeq M_E$. For every field extension, K/E , $N \otimes_E K \simeq M_K$ is simple.

(3) The second assertion follows from the first one applied to an algebraic closure of F . Let M'_1, \dots, M'_r be a system of representatives of isomorphism classes of simple A_K -modules. Choose an F -linear bases (a_ℓ) and $(m_i^{(k)})$ of A and $(M'_k)_K$ and write $a_\ell m_i^{(k)} = \sum_j c_{\ell,i,j}^{(\ell)} m_j^{(k)}$ with $c_{\ell,i,j}^{(\ell)} \in \bar{F}$. Let E be the subextension of K/F generated by $c_{\ell,i,j}^{(\ell)}$. Then E/F is finite and we get A_E -modules M_k with $M_k \otimes_E \bar{F} \simeq M'_k$. Then M_k is absolutely simple. Let M be a simple A_E -module. Then $\text{Hom}_{A_E}(M, M_k) \otimes_E K \simeq \text{Hom}_{A_K}(M \otimes_E K, (M_k) \otimes_E K)$ is nonzero for some k . It follows that $M \simeq M_k$ as A_E -module. \square

Proposition 4.2.9. *Let A and B be split finite-dimensional F -algebras. Then $A \otimes_F B$ is split over F and every simple $A \otimes_F B$ -module is isomorphic to $M \otimes_F N$, where M is a simple A -module and N is a simple B -module.*

In particular, if G and H are finite group split over F , then $G \times H$ is split over F and every irreducible representations of $G \times H$ over F is of the form $\rho \boxtimes \sigma$, where ρ and σ are irreducible representations of G and H over F , respectively.

Proof. Every simple $A \otimes_F B$ -module P is a Jordan–Hölder factor of ${}_{A \otimes_F B} A \otimes_F B$, and hence a Jordan–Hölder factor of $M \otimes_F N$ for some simple A -module M and some simple B -module N . By Corollary 4.2.5, $M \otimes_F N$ is absolutely simple. Thus P is isomorphic to $M \otimes_F N$ for some M and N as above. \square

Semisimplicity and field extensions

This subsection will not be used in the sequel.

Proposition 4.2.10. *Let M be a semisimple A -module with $\dim_F M < \infty$ and let E/F be a separable extension. Then M_E is a semisimple A_E -module.*

Proof. Let B be the image of A in $\text{End}_F(M)$. Then $\dim_F B < \infty$ and B is a semisimple F -algebra by Propositions 3.5.2 and 3.5.4. Then M_E is a semisimple B_E -module by case (b) of Proposition 4.2.11 below. It follows that M_E is a semisimple A_E -module. \square

Proposition 4.2.11. *Let $A \simeq \prod_{i=1}^r M_{n_i}(D_i)$ be a finite-dimensional semisimple F -algebra, where each D_i is a division F -algebra. Let E/F be a field extension. Assume that (a) each $Z(D_i)/F$ is separable or (b) E/F is separable. Then A_E is a semisimple E -algebra.*

Proof. We have $A_E \simeq \prod_{i=1}^r M_{n_i}((D_i)_E)$. Thus we may assume that $A = D$ is a division F -algebra. Then $D \otimes_F E \simeq D \otimes_{Z(D)} Z(D) \otimes_F E$. By the lemma below $Z(D) \otimes_F E \simeq \bigoplus_{j=1}^m L_j$, where each L_j is a field. Then $D \otimes_F E \simeq \bigoplus_{j=1}^m D \otimes_{Z(D)} L_j$, where each $D \otimes_{Z(D)} L_j$ is a central simple L_j -algebra by Proposition 3.7.8. \square

Remark 4.2.12. It follows from the proof that if A is a central simple $Z(A)$ -algebra of degree d with $[Z(A) : F] < \infty$ and satisfying (a) or (b) above, then $A \otimes_F E \simeq \prod_{j=1}^m B_j$, where each B_j is a central simple $Z(B_j)$ -algebra of degree d . If, moreover, E is a splitting field of A , then $A \otimes_F E \simeq \prod_{j=1}^m M_d(E)$. In this case, we have $m = [Z(A) : F]$ by dimension count.

Lemma 4.2.13. *Let E/F and K/F be field extensions with E/F separable. Assume that (a) E/F is finite or (b) K/F is finite. Then $E \otimes_F K \simeq \prod_{j=1}^m L_j$ with each L_j a separable field extension of K .*

Proof. (a) We have $E = F(x) \simeq F[X]/(P(X))$ (either by the primitive element theorem or by reduction to the case of a simple extension), where $P(X) \in F[X]$ is a separable polynomial. Let $P(X) = \prod_{j=1}^m Q_j(X)$ with $Q_j(X) \in E[X]$ irreducible. Then $E \otimes_F K \simeq \prod_{j=1}^m K[X]/(Q_j(X))$.

(b) We reduce easily to two cases: K/F separable or purely inseparable. If K/F is separable, then applying (a), we get $E \otimes_F K \simeq \prod_{j=1}^m L_j$ with L_j separable over F . If E/F is purely inseparable, then E/F and K/F are linearly disjoint (Example 3.1.13) and $E \otimes_F K$ is a field separable over K by Remark 3.1.9. \square

Remark 4.2.14. By case (a), for any finite étale commutative F -algebra A (Definition 1.17.25), A_E is a finite étale commutative E -algebra.

Proposition 4.2.15. *Let A be a finite dimensional F -algebra. The following conditions are equivalent:*

- (1) *For every field extension E/F , A_E is semisimple.*
- (2) *For an algebraic closure \bar{F} of F , $A_{\bar{F}}$ is semisimple.*
- (3) *$A \simeq \prod_{i=1}^r M_{n_i}(D_i)$, where each D_i is a division F -algebra with $Z(D_i)/F$ separable.*

Under Condition (3), A splits over any Galois extension of E/F containing all $Z(D_i)$, and, in particular, over a finite separable extension of F .

Proof. (1) \Rightarrow (2). Trivial.

(2) \Rightarrow (3). By the Wedderburn–Artin theorem, we have $A \simeq \prod_{i=1}^r M_{n_i}(D_i)$. Moreover, $Z((D_i)_{\bar{F}}) \simeq Z(D_i) \otimes_F \bar{F}$ by Proposition 3.7.8, so that $Z(A_{\bar{F}}) \simeq \prod_{i=1}^r Z(D_i) \otimes_F \bar{F}$. If $Z(D_i)/F$ is not separable, then $Z(D_i) \otimes_F \bar{F}$ is not reduced (exercise), and we get a nonzero nilpotent element $x \in Z(A_{\bar{F}})$. Then $Ax \subseteq \text{rad}(A_{\bar{F}})$, contradicting the semisimplicity of $A_{\bar{F}}$.

(3) \Rightarrow (1). This is case (a) of Proposition 4.2.11.

For the last two assertions, note that, in the proof of Proposition 4.2.11, $Z(D) \otimes_F E$ is a finite product of E by Example 3.8.2 under the assumption that $Z(D) \subseteq E$ and E/F Galois. Thus we may assume that $Z(D_i) = F$ for all i . Then it suffices to take E/F to be a finite separable extension containing a maximal subfield of D_i containing F for each i . \square

Combined with Maschke’s theorem, we obtain the following result.

Corollary 4.2.16. *Let G be a finite group satisfying $\text{char}(F) \nmid \#G$. Then G splits over a finite separable extension of F .*

Linear independence of matrix coefficients

Theorem 4.2.17 (Frobenius–Schur). *Let A be an F -algebra, M_1, \dots, M_r absolutely simple left A -modules such that $\dim_F M_k < \infty$ for all k and $M_k \not\cong M_\ell$ for $k \neq \ell$. Choose F -linear bases $(m_i^{(k)})_{1 \leq i \leq n_k}$ of M_k and $(\check{m}_j^{(k)})_{1 \leq j \leq n_k}$ of $\check{M}_k := \text{Hom}_F(M_k, F)$. Then the functions*

$$c_{i,j}^{(k)} : A \rightarrow F \quad a \mapsto \check{m}_j^{(k)}(am_i^{(k)}),$$

where $1 \leq k \leq r$, $1 \leq i, j \leq n_k$ are F -linearly independent.

Proof. Let $M = \bigoplus_{k=1}^r M_k$. Let B be the image of A in $\text{End}_F(M)$. Then B is a finite-dimensional semisimple F -algebra by Propositions 3.5.2 and 3.5.4 and M_1, \dots, M_r are pairwise nonisomorphic absolutely simple B -modules. By Theorem 4.2.3, $\text{End}_B(M) = F^r$. By the Jacobson density theorem, $\lambda : B \rightarrow \prod_{k=1}^r \text{End}_F(M_k)$ is a surjection. By the definition of B , λ is an injection. Thus λ is an isomorphism. (One can also deduce this from the Wedderburn–Artin theorem.) The functions $c_{i,j}^{(k)}$ factor through B and form a basis of $\text{Hom}_F(B, F)$. \square

Corollary 4.2.18. *Let G be a group, $(V_1, \rho_1), \dots, (V_r, \rho_r)$ absolutely irreducible finite-dimensional representations of G over F . Choose F -linear bases $(v_i^{(k)})_{1 \leq i \leq n_k}$ of V_k and $(\check{v}_j^{(k)})_{1 \leq j \leq n_k}$ of \check{V}_k . Then the functions*

$$c_{i,j}^{(k)} : G \rightarrow F \quad g \mapsto \check{v}_j^{(k)}(\rho_k(g)v_i^{(k)}),$$

where $1 \leq k \leq r$, $1 \leq i, j \leq n_k$ are F -linearly independent.

The corollary holds in fact for monoids and generalize the linear independence of degree one characters (Lemma 1.13.6).

Characters

Definition 4.2.19. Let A be an F -algebra and M a left A -module with $\dim_F M < \infty$. We call the F -linear map

$$\chi_M: A \rightarrow F \quad a \mapsto \text{tr}(a, M)$$

the *character* of M .

Remark 4.2.20. (1) Let $0 \rightarrow M' \rightarrow M \rightarrow M'' \rightarrow 0$ be a short exact sequence of A -modules. Then $\chi_M = \chi_{M'} + \chi_{M''}$. In particular, χ_M depends only on the isomorphism class of M . Moreover, χ_M vanishes on $\text{rad}(A)$, since the same holds for χ_N with N simple.

(2) Let $[A, A] \subseteq A$ be the additive subgroup generated by elements of the form $ab - ba$, $a, b \in A$, which is an F -linear subspace (but *not* an ideal in general). Then χ_M vanishes on $[A, A]$.

Corollary 4.2.21 (Linearly independence of characters). *The characters of the isomorphism classes of absolutely simple left A -modules M_k with $\dim_F M_k < \infty$ are F -linearly independent.*

In particular, for absolutely simple left A -modules M and M' , $\chi_M = \chi_{M'}$ if and only if $M \simeq M'$.

Proof. In Theorem 4.2.17, we take $(\check{m}_i^{(k)})$ to be a dual basis of $(m_i^{(k)})$. Then $\chi_{M_k} = \sum_{i=1}^{n_k} c_{i,i}^{(k)}$. \square

The corollary has the following variant.

Proposition 4.2.22. *Assume that $\text{char}(F) = 0$. The characters of the isomorphism classes of simple left A -modules M_k with $\dim_F M_k < \infty$ are F -linearly independent. In particular, for left A -modules M and M' , $\chi_M = \chi_{M'}$ if and only if $\text{JH}(M) = \text{JH}(M')$.*

Proof. It suffices to prove the first assertion. As in Theorem 4.2.17, we may assume that $\dim_F A < \infty$. By the Wedderburn–Artin theorem, $A = \bigoplus_{i=1}^r A_k$, where $A_k = \text{End}_{D_k}(M_k)$, $D_k = \text{End}_A(M_k)$, M_1, \dots, M_r is a system of representatives of isomorphism classes of simple A -modules. Let $e_k \in A$ be the idempotent corresponding to A_k , so that $e_k|_{M_\ell} = \delta_{k,\ell}$. Then $\chi_{M_k}(e_\ell) = 0$ for $k \neq \ell$ and $\chi_{M_k}(e_k) = \dim_F M_k \neq 0$. \square

Definition 4.2.23. Let G be a group and (V, ρ) a finite-dimensional linear representation of G over F . We call the function

$$\chi_{(V, \rho)}: G \rightarrow F \quad g \mapsto \text{tr}(\rho(g))$$

the character of (V, ρ) .

If $\chi = \chi_{(V, \rho)}$, then $\chi(hgh^{-1}) = \chi(g)$. In other words, it is constant on conjugacy classes of G . A function $G \rightarrow F$ satisfying this condition is called a *class function* (or central function) on G . We let $\text{ClassFunc}(G, F)$ denote the F -vector space of class functions $G \rightarrow F$. For $A = F[G]$, restriction via the embedding $G \hookrightarrow F[G]$ induces an isomorphism $\text{Hom}_F(A/[A, A], F) \xrightarrow{\sim} \text{ClassFunc}(G, F)$.

Warning 4.2.24. $\chi_{(V,\rho)}$ is in general *nonconstant* on the commutator subgroup $[G, G]$.

Remark 4.2.25. (1) If $\dim_F V = 1$, then $\chi_{(V,\rho)} = \rho$.
 (2) $\chi_V(1) = \dim_F V$. This is called the *dimension* (or *degree*) of χ_V .
 (3) $\chi_{\rho \otimes \rho'}(g) = \chi_\rho(g)\chi_{\rho'}(g)$.
 (4) $\chi_{\bar{\rho}}(g) = \chi_\rho(g^{-1})$.
 (5) Assume that G is finite. Then $\chi_\rho(g)$ is a sum of roots of unity (in a separable closure of F). Moreover, for $F = \mathbb{C}$, $\chi_\rho(g^{-1})$ is the complex conjugate of $\chi_\rho(g)$.

Example 4.2.26. If G is a finite group and reg denotes the regular representation of G , then $\chi_{\text{reg}}(g) = \begin{cases} \#G & g = 1 \\ 0 & g \neq 1. \end{cases}$

Corollary 4.2.21 and Proposition 4.2.22 apply to characters as follows. The character of an (absolutely) irreducible representation is said to be (absolutely) irreducible.

Corollary 4.2.27. *Let G be a group. The absolutely irreducible characters of G over F are F -linearly independent. If $\text{char}(F) = 0$, then the irreducible characters of G over F are F -linearly independent and finite-dimensional representations V and V' satisfy $\chi_V = \chi_{V'}$ if and only if $\text{JH}(V) \simeq \text{JH}(V')$.*

4.3 Characters of finite groups

Let G be a finite group and F a field.

Assumption 4.3.1. In this section, we assume $\text{char}(F) \nmid \#G$. By Maschke's theorem, this is equivalent to assuming that $F[G]$ is semisimple.

Proposition 4.3.2. *Let V_1, \dots, V_r be a system of representatives of irreducible representations of G over F . Let K/F be a field extension such that K is a splitting field of G . Then $(V_i)_K \simeq \bigoplus_{j=1}^{t_i} W_{i,j}^{\oplus d_i}$, where $D_i = \text{End}_{F[G]}(V_i)$, $t_i = [Z(D_i) : F]$, $d_i^2 = \dim_{Z(D_i)}(D_i)$, and $W_{i,j}$, $1 \leq i \leq r$, $1 \leq j \leq t_i$, form a system of representatives of irreducible representations of G over K . Moreover, if K/F is finite, then $t_i d_i \mid [K : F]$ for every i .*

The number d_i is called the *Schur index* of V_i .

Proof. By the Wedderburn–Artin theorem, $F[G] \simeq \prod_{i=1}^r A_i$, where $A_i = \text{End}_{D_i}(V_i) \simeq M_{n_i}(D_i^{\text{op}})$. Note that A_i is a central simple $Z(D_i)$ -algebra of degree $n_i d_i$. By Proposition 4.2.15, $Z(D_i)/F$ is separable. Thus, by Remark 4.2.12, $(A_i)_K \simeq \prod_{j=1}^{t_i} M_{n_i d_i}(K)$. By Proposition 3.7.35, $d_i \mid [K : Z(D_i)] = \frac{[K:F]}{t_i}$, where $Z(D_i)$ is regarded as a subfield of K via the j -th embedding. \square

If n_i denotes the multiplicity of V_i in the regular representation of G over F , then the regular representation of G over K takes the form $\bigoplus_{i=1}^r \bigoplus_{j=1}^{t_i} W_{i,j}^{\oplus n_i d_i}$, so that $\dim_K W_{i,j} = d_i n_i$, and $\#G = \sum_{i=1}^r t_i (d_i n_i)^2$.

Corollary 4.3.3. $\chi_{V_1}, \dots, \chi_{V_r}$ are F -linearly independent. Moreover, $\text{char}(F) \nmid d_i$.

In particular, for irreducible representations V and V' of G over F , $\chi_V = \chi_{V'}$ if and only if $V \simeq V'$. We have already seen some special cases in the previous section.

Proof. We have $\chi_{V_i} = d_i \sum_{j=1}^{t_i} \chi_{W_{i,j}}$. Since $\chi_{V_i} \neq 0$, $\text{char}(F) \nmid d_i$. Since $W_{i,j}$ are absolutely irreducible, $\chi_{W_{i,j}}$ are linearly independent. \square

Let K/F be a field extension. We say that a representation W of G over K can be realized over F if there exists a representation V of G over F such that $V_K \simeq W$.

Corollary 4.3.4. Let K/F be a field extension such that K is a splitting field of G . Then F is a splitting field of G if and only if every irreducible representation of G over K is realizable over F .

Proof. The “only if” part follows from Proposition 4.2.6. For the “if” part, there exist representations $V_{i,j}$ of G over F such that $(V_{i,j})_K \simeq W_{i,j}$. Then $V_{i,j}$ is absolutely irreducible. Since $\chi_{V_{i,j}} = \chi_{W_{i,j}}$, we have $\chi_{V_i} = d_i \sum_{j=1}^{t_i} \chi_{V_{i,j}}$. By the previous lemma, $t_i = 1$ and $V_i \simeq V_{i,1}$. Thus V_i is absolutely irreducible. \square

Next we strengthen the independence of characters. Let $\chi, \chi': G \rightarrow F$ be functions. We define

$$\langle \chi, \chi' \rangle = \frac{1}{\#G} \sum_{g \in G} \chi(g) \chi'(g^{-1}) \in F.$$

This is a symmetric and F -bilinear form.

Theorem 4.3.5 (First orthogonality relation for characters). Let V and V' be irreducible representations of G over F . Then

$$\langle \chi_V, \chi_{V'} \rangle = \begin{cases} \dim_F(\text{End}_{F[G]}(V)) & V \simeq V' \\ 0 & V \not\simeq V'. \end{cases}$$

Let V_1, \dots, V_r be a system of representatives of the isomorphism classes of irreducible representations of G over F . Then, by the Wedderburn–Artin theorem,

$$(4.3.1) \quad F[G] \simeq \prod_{i=1}^r \text{End}_{D_i}(V_i),$$

where $D_i = \text{End}_{F[G]}(V_i)$. Then $1 = \sum_i e_i$ with $e_i \in \text{End}_{D_i}(V_i)$ $e_i|_{V_j} = \delta_{i,j}$.

Lemma 4.3.6. Let V be an irreducible representation of V and let e_V be the corresponding idempotent element in the above decomposition. Let n_V be the multiplicity of V in the regular representation. Then

$$e_V = \frac{n_V}{\#G} \sum_{g \in G} \chi_V(g^{-1})g.$$

In particular, $\text{char}(F) \nmid n_V$.

Proof. Let χ_{reg} be the character of $_{F[G]}F[G]$. Write $e_V = \sum_{h \in G} a_h h$. Then

$$\chi_{\text{reg}}(e_V g^{-1}) = \sum_{h \in G} a_h \chi_{\text{reg}}(hg^{-1}) = a_g \#G.$$

On the other hand, $\chi_{\text{reg}}(e_V c) = n_V \chi_V(c)$. In particular, $\chi_{\text{reg}}(e_V g^{-1}) = n_V \chi_V(g^{-1})$. Thus $a_g = \frac{n_V}{\#G} \chi_V(g^{-1})$. The last assertion follows from the fact that $e_V \neq 0$. \square

Proof of Theorem 4.3.5. By the lemma, $\langle \chi_V, \chi_{V'} \rangle = \frac{1}{n_V} \chi_{V'}(e_V)$. For $V \not\cong V'$, $\chi_{V'}(e_V) = 0$. For $V \cong V'$, $\chi_{V'}(e_V) = \chi_{V'}(1) = \dim_F V$. Finally, $\dim_F V = n_V \dim_F D$, where $D = \text{End}_{F[G]}(V)$. \square

Corollary 4.3.7. *Let W and W' be finite-dimensional representations of G over F . Then $\langle \chi_W, \chi_{W'} \rangle = \dim_F \text{Hom}_{F[G]}(W, W')$.*

Proof. Since W and W' are semisimple, we may assume that they are irreducible. In this case, the equality is the first orthogonality relation. \square

Corollary 4.3.8. *Assume $\text{char}(F) = 0$.*

- (1) *For finite-dimensional representations W and W' , $\chi_W = \chi_{W'}$ if and only if $W \cong W'$.*
- (2) *For $\chi = \sum_V m_V \chi_V$, where χ_V runs through irreducible characters and $m_V \in F$, we have $m_V = \langle \chi, \chi_V \rangle / \dim_F(\text{End}_{F[G]}(V))$.*
- (3) *A finite-dimensional representation W is absolutely irreducible if and only if $\langle \chi_W, \chi_W \rangle = 1$.*

Proof. (1) This follows from Corollary 4.2.27.

(2) This follows from the theorem.

(3) This follows from Corollary 4.3.7. \square

Next we study the space of class functions.

Lemma 4.3.9. *Let H be a group. For each finite conjugacy class C of H , let $s_C := \sum_{g \in C} g \in F[H]$. Then the s_C form an F -linear basis of $Z(F[H])$.*

In other words, the map

$$Z(F[H]) \rightarrow \text{Map}(H, F) \quad \sum_g a_g g \mapsto (g \mapsto a_g)$$

identifies $Z(F[H])$ with class functions with finite support.

Proof. Let $c = \sum_g a_g g \in F[H]$. Then $c \in Z(F[H])$ if and only if $ch = hc$ for all $h \in H$. Note that $hch^{-1} = \sum_g a_g hgh^{-1}$. Thus $c \in Z(F[H])$ if and only if $a_{hgh^{-1}} = a_g$ for all $g, h \in H$. In other words, $c \in Z(F[H])$ if and only if a_g is constant on every conjugacy class of H . \square

By (4.3.1), $Z(F[G]) \simeq \prod_{i=1}^r Z(D_i)$. Let s be the number of conjugacy classes of G , which is also $\dim_F \text{ClassFunc}(G, F)$. It follows then from the lemma that

$$s = \sum_{i=1}^r [Z(D_i) : F].$$

We have proved the following.

Theorem 4.3.10. *The following conditions are equivalent:*

- (1) $Z(D_i) = F$;
- (2) $r = s$;
- (3) *The irreducible characters form an F -linear basis of $\text{ClassFunc}(G, F)$.*

These conditions are satisfied if G splits over F .

For each conjugacy class C of G , we let $\mathbf{1}_C$ denote the indicator function of $C \subseteq G$. Then $(\mathbf{1}_C)_C$ form a basis of $\text{ClassFunc}(G, F)$. For G split over F , the transition matrix between the from the basis $(\chi_V)_V$ to the basis $(\mathbf{1}_C)_C$ can be given as follows.

Theorem 4.3.11 (Second orthogonality relation for characters). *Assume that G is split over F . Then for $g, h \in G$,*

$$(4.3.2) \quad \sum_V \chi_V(g)\chi_V(h^{-1}) = \begin{cases} \frac{\#G}{\#C} & \text{if } g, h \text{ belong to the same conjugacy class } C \\ 0 & \text{otherwise.} \end{cases}$$

Here V runs through isomorphism classes of irreducible representations of G over F .

In other words,

$$\sum_V \chi_V(g)\chi_V(h^{-1}) = \sum_C \frac{\#G}{\#C} \mathbf{1}_C(g)\mathbf{1}_C(h) = \frac{\#G}{\#C_h} \mathbf{1}_{C_h}(g),$$

where C runs through conjugacy classes of G , and C_h denotes the conjugacy class of h . Moreover, $\#G/\#C_h = \#Z_G(h)$, where $Z_G(h) = \{g \in G \mid gh = hg\}$ denotes the centralizer of h in G .

One way to prove the second orthogonality is via the following bimodule version of the Wedderburn–Artin theorem.

Theorem 4.3.12. *Let R be a semisimple ring. Then ${}_R R_R \simeq \bigoplus_{i=1}^r M_i \otimes_{D_i^{\text{op}}} M'_i$, where M_1, \dots, M_r is a system of representatives of the isomorphism classes of simple left R -modules, $D_i = \text{End}_R(M_i)$, $M'_i = \text{Hom}_{D_i}(M_i, D_i)$.*

Corollary 4.3.13. *Assume that G is split over F . Let $G \times G$ act on $F[G]$ by $\rho(g, h): x \mapsto gxh^{-1}$. Then*

$$(4.3.3) \quad (F[G], \rho) \simeq \bigoplus_V V \boxtimes \check{V},$$

where V runs through isomorphism classes of irreducible representations of G over F .

Proof of Theorem 4.3.11. This follows from evaluating the traces of (g, h) on both sides of (4.3.3). Note that $\rho(g, h)$ permutes the basis G of $F[G]$, so that $\text{tr}(\rho(g, h))$ equals the cardinality of the fixed point set $\{x \in G \mid gxh^{-1} = x\}$, which equals the righthand side of (4.3.2). \square

Let us summarize some character formulas for G split over F : we have $r = s$, $n_i = \dim_F V_i$, $\#G = \sum_{i=1}^r n_i^2$, $\chi_{\text{reg}} = \sum_{i=1}^r n_i \chi_i$, and $\chi_i(1) = n_i$ (in F). Moreover, $\langle \chi_i, \chi_j \rangle = \delta_{i,j}$.

Example 4.3.14. Let $G = \Sigma_3$ with $\#\Sigma_3 = 6$. There are three conjugacy classes:

$$\{e\}, \quad \{(12), (13), (23)\}, \quad \{(123), (132)\}.$$

There are two obvious characters of dimension 1: $\chi_0 = \mathbf{1}$ and $\chi_1 = \text{sgn}$. We denote the remaining irreducible character by θ . Assume that G is split over F . Then $6 = 1^2 + 1^2 + n_\theta^2$, so that $n_\theta = 2$. We deduce θ from $\chi_{\text{reg}} = \chi_0 + \chi_1 + 2\theta$. Here is the table of irreducible characters of Σ_3 .

g	e	$(12), (13), (23)$	$(123), (132)$
$\#C_g$	1	3	2
$\chi_0(g)$	1	1	1
$\chi_1(g)$	1	-1	1
$\theta(g)$	2	0	-1

The character θ is the character of the obvious representation of Σ_3 on $V = \ker(F^3 \xrightarrow{\Sigma} F)$, called the *standard representation* of Σ_3 , which must be irreducible. It follows that Σ_3 splits over any field of characteristic $\neq 2, 3$.

The first orthogonality is the orthogonality of the rows of the character table, weighted by $\#C$. The second orthogonality is the orthogonality of the columns.

We have $V \otimes V \simeq (F, \chi_0) \oplus (F, \chi_1) \oplus V$. Indeed, if $V \otimes V \simeq (F, \chi_0)^{\oplus m_0} \oplus (F, \chi_1)^{\oplus m_1} \oplus V^{\oplus m_V}$, then $\chi_V^2 = m_0\chi_0 + m_1\chi_1 + m_V\theta$, which implies $m_0 \equiv m_1 \equiv 1 \pmod{\text{char}(F)}$ and $m_V \equiv 1 \pmod{\text{char}(F)}$. We conclude by $m_0, m_1, 2m_V \leq 4 = \dim_F V$ and $\text{char}(F) \neq 2, 3$.

Example 4.3.15. Let $G = A_4$ be the alternating group with $\#A_4 = 12$. There are four conjugacy classes:

$$\{e\}, \quad C = \{(12)(34), (13)(24), (14)(23)\}, \\ \{(123), (134), (142), (243)\}, \quad \{(132), (124), (143), (234)\}.$$

Assume that F contains a primitive cube root of unity ω . Recall that $V = \{e\} \cup C$ is a normal subgroup of A_4 . The quotient A_4/V is cyclic of order 3, and thus has three characters of dimension 1. Inflation gives us three characters $\chi_0 = \mathbf{1}, \chi_1, \chi_2$ of A_4 of dimension 1. Assume that G is split over F . We denote the remaining irreducible character by θ . Then $12 = 1^2 + 1^2 + 1^2 + n_\theta^2$, so that $n_\theta = 3$. We deduce θ from $\chi_{\text{reg}} = \chi_0 + \chi_1 + \chi_2 + 3\theta$. Here is the character table of A_4 :

g	e	$(12)(34)$	(123)	(132)
$\#C_g$	1	3	4	4
$\chi_0(g)$	1	1	1	1
$\chi_1(g)$	1	1	ω	ω^2
$\chi_2(g)$	1	1	ω^2	ω
$\theta(g)$	3	-1	0	0

The character θ is the character of the obvious representation of A_4 on $V = \ker(F^4 \xrightarrow{\Sigma} F)$, which must be irreducible. It follows that A_4 splits over a field of characteristic $\neq 2, 3$ if and only if it contains a primitive cube root of unity.

Example 4.3.16. Let $G = D_n$ be the dihedral group of order $2n$. We have $D_n = \langle r, s \mid r^n = 1, s^2 = 1, srs = r^{-1} \rangle$. Every element of D_n is of the form r^k or sr^k , for $0 \leq k \leq n-1$. Assume that F contains a primitive n -th root of unity ζ . Then, for $h \in \mathbb{Z}$, we have representations $\rho_h: D_n \rightarrow \text{GL}_2(F)$ given by

$$\rho_h(r^k) = \begin{pmatrix} \zeta^{hk} & 0 \\ 0 & \zeta^{-hk} \end{pmatrix}, \quad \rho_h(sr^k) = \begin{pmatrix} 0 & \zeta^{-hk} \\ \zeta^{hk} & 0 \end{pmatrix}.$$

For $0 < h < n/2$, $\zeta^h \neq \zeta^{-h}$, so that the only lines stabilized by $\rho_h(r)$ are the coordinate axes, which are not stabilized by $\rho_h(s)$. Thus, for such h , ρ_h is (absolutely) irreducible. We let χ_h denote the character of ρ_h . The χ_h for $0 < h < n/2$ are distinct. In fact, if $a = \zeta^h + \zeta^{-h}$, then ζ^h and ζ^{-h} are the only roots of $X^2 - aX + 1$. There are two characters of dimension 1, ψ_1 and ψ_2 .

For n odd, these exhaust all the irreducible representations up to isomorphism: $2 \times 1^2 + \frac{n-1}{2} \times 2^2 = 2n$. For n even, there are two more characters of dimension 1, ψ_3 and ψ_4 : $4 \times 1^2 + (\frac{n}{2} - 1) \times 2^2 = 2n$. Here is the character table for D_n :

	g	r^k	sr^k
	$\psi_1(g)$	1	1
	$\psi_2(g)$	1	-1
(n even)	$\psi_3(g)$	$(-1)^k$	$(-1)^k$
(n even)	$\psi_4(g)$	$(-1)^k$	$(-1)^{k+1}$
	$\chi_h(g)$	$\zeta^{kh} + \zeta^{-kh}$	0

We have $(F^2, \rho_0) \simeq (F, \psi_1) \oplus (F, \psi_2)$ and, if n is even, $(F^2, \rho_{n/2}) \simeq (F, \psi_3) \oplus (F, \psi_4)$.

Some other useful forms of ρ_h are (assuming $\zeta^h \neq \pm 1$ for ρ_h'')

$$\begin{aligned} \rho_h'(r^k) &= \begin{pmatrix} \cos \frac{2hk\pi}{n} & -\sin \frac{2hk\pi}{n} \\ \sin \frac{2hk\pi}{n} & \cos \frac{2hk\pi}{n} \end{pmatrix}, & \rho_h'(sr^k) &= \begin{pmatrix} \cos \frac{2hk\pi}{n} & -\sin \frac{2hk\pi}{n} \\ -\sin \frac{2hk\pi}{n} & -\cos \frac{2hk\pi}{n} \end{pmatrix}; \\ \rho_h''(r) &= \begin{pmatrix} 0 & -1 \\ 1 & \zeta^h + \zeta^{-h} \end{pmatrix}, & \rho_h''(s) &= \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}. \end{aligned}$$

Here $\cos \frac{2\pi}{n} = \frac{\zeta + \zeta^{-1}}{2}$ and $\sin \frac{2\pi}{n} = \frac{\zeta - \zeta^{-1}}{2i}$. We have

$$\rho_h''(g) = \begin{pmatrix} 1 & -\zeta^h \\ -\zeta^h & 1 \end{pmatrix} \rho_h(g) \begin{pmatrix} 1 & -\zeta^h \\ -\zeta^h & 1 \end{pmatrix}^{-1}$$

for $g \in D_n$. It follows that a field of characteristic $\nmid 2n$ splits D_n if and only if it contains $\zeta + \zeta^{-1}$. In particular, D_1, D_2, D_4 split over any field of characteristic $\neq 2$ and D_3, D_6 split over any field of characteristic $\neq 2, 3$.

4.4 Induced representations

Remark 4.4.1. Let $f: S \rightarrow R$ be a morphism of rings. Restriction of scalars gives a functor $f^*: R\text{-Mod} \rightarrow S\text{-Mod}$, which admits a left adjoint

$$f_!: S\text{-Mod} \rightarrow R\text{-Mod}, \quad {}_S M \mapsto R \otimes_S M$$

and a right adjoint

$$f_*: S\text{-Mod} \rightarrow R\text{-Mod}, \quad {}_S M \mapsto \text{Hom}_S(R, M).$$

For ${}_S M$ and ${}_R N$, we have isomorphisms, special cases of Remark 2.7.10:

$$\begin{aligned} \text{Hom}_R(R \otimes_S M, N) &\simeq \text{Hom}_S(M, f^*N) \\ \alpha &\mapsto (m \mapsto \alpha(1 \otimes m)) \\ (r \otimes m \mapsto r\beta(m)) &\leftrightarrow \beta, \\ \text{Hom}_S(f^*N, M) &\simeq \text{Hom}_R(N, \text{Hom}_S(R, M)) \\ \alpha &\mapsto (n \mapsto (r \mapsto \alpha(rn))) \\ (n \mapsto \beta(n)(1)) &\leftrightarrow \beta. \end{aligned}$$

We fix a field F . Let $\phi: H \rightarrow G$ be a homomorphism of groups, inducing a homomorphism of F -algebras $F[\phi]: F[H] \rightarrow F[G]$. Translating the above into the language of representations, the pullback functor $\phi^*: \mathbf{Rep}_F(G) \rightarrow \mathbf{Rep}_F(H)$ admits a left adjoint

$$\phi_!: \mathbf{Rep}_F(H) \rightarrow \mathbf{Rep}_F(G), \quad V \mapsto F[G] \otimes_{F[H]} V$$

and a right adjoint

$$\phi_*: \mathbf{Rep}_F(H) \rightarrow \mathbf{Rep}_F(G), \quad V \mapsto \text{Hom}_{F[H]}(F[G], V).$$

Proposition 4.4.2 (Frobenius reciprocity). *Let V and W be representations of H and G over F , respectively. Then we have canonical isomorphisms*

$$\begin{aligned} \text{Hom}_{F[G]}(\phi_! V, W) &\simeq \text{Hom}_{F[H]}(V, \phi^* W), \\ \text{Hom}_{F[H]}(\phi^* W, V) &\simeq \text{Hom}_{F[G]}(W, \phi_* V). \end{aligned}$$

These functors are transitive in the following sense: For a sequence $P \xrightarrow{\psi} H \xrightarrow{\phi} G$ be homomorphisms of groups, we have $(\phi\psi)^* = \psi^*\phi^*$ by definition. Moreover, we have canonical isomorphisms $(\phi\psi)_* \simeq \phi_*\psi_*$ and $(\phi\psi)_! \simeq \phi_!\psi_!$.

Restriction via the inclusion $G \hookrightarrow F[G]$ induces an isomorphism

$$\phi_*(V, \rho) \xrightarrow{\sim} \{f: G \rightarrow V \mid f(\phi(h)g) = \rho(h)f(g), \forall h \in H, g \in G\}.$$

G acts on the righthand side by right translation: $(gf)(g') = f(g'g)$. In the sequel we will identify $\phi_*(V, \rho)$ with the righthand side.

Every ϕ can be decomposed into a surjective homomorphism, followed by an inclusion.

Remark 4.4.3. Assume that $\phi: H \rightarrow G$ is a surjective homomorphism. Let $K = \ker(\phi)$. Then we have an isomorphism

$$\begin{aligned} \phi_*(V, \rho) &\simeq V^K \\ f &\mapsto f(1) \\ (h \mapsto \rho(h)v) &\leftrightarrow v. \end{aligned}$$

Here $V^K \subseteq V$ denotes the subspace of K -invariants. On the other hand, $F[G] \simeq F[H]/I$, where I is the ideal generated by $k-1$, $k \in K$. Thus $\phi_!(V, \rho) \simeq V_K := V/IV$, which is called the space of K -coinvariants. Here $IV \subseteq V$ is the F -linear subspace generated by $\rho(k)v - v$ for $k \in K$, $v \in V$.

In the sequel we assume that H is a subgroup of G and that $\phi: H \hookrightarrow G$ is the inclusion.

Definition 4.4.4. We write res_H^G for ϕ^* , Ind_H^G for ϕ_* , and ind_H^G for $\phi_!$. We call $\text{Ind}_H^G(V)$ the *induced representation* and $\text{ind}_H^G(V)$ the *compactly induced representation*.¹

The terminology and notation is somewhat explained by the following.

Proposition 4.4.5. *The homomorphism of representations of G*

$$\text{ind}_H^G(V) \rightarrow \text{Ind}_H^G(V) \quad g \otimes v \mapsto \left(g' \mapsto \begin{cases} g'gv & g'g \in H \\ 0 & \text{otherwise} \end{cases} \right)$$

is an injection and its image consists precisely of those maps $f: G \rightarrow V$ in $\text{Ind}_H^G(V)$ that are supported on the union of finitely many right cosets of H . In particular, if H has finite index in G , then $\text{ind}_H^G(V) \xrightarrow{\sim} \text{Ind}_H^G(V)$.

Proof. The inverse from the subspace of maps finitely supported modulo H to $\text{ind}_H^G(V)$ is given by $f \mapsto \sum_{\bar{g} \in G/H} g \otimes f(g^{-1})$, where g is a representative of the coset \bar{g} . \square

Remark 4.4.6. Let S be a set of representatives of $H \backslash G$. As F -vector spaces $\text{Ind}_H^G(V) \simeq \text{Map}(S, V) = V^S$ and $\text{ind}_H^G(V) \simeq V^{\oplus S}$. In particular, $\dim_F \text{ind}_H^G(V) = (G : H) \dim_F(V)$.

Example 4.4.7. $\text{ind}_{\{1\}}^H(\mathbf{1}) \simeq F[H]$ is the regular representation. For every character χ of H of dimension 1, we have a surjective homomorphism of F -algebras $F[H] \rightarrow F$ carrying h to $\chi(h)$, whose kernel is the ideal generated by $h - \chi(h)$. This gives a morphism $\phi: \text{ind}_{\{1\}}^H(\mathbf{1}) \rightarrow (F, \chi)$ of representations of H , corresponding to the identity map $\mathbf{1} \simeq \text{res}_{\{1\}}^H \chi$ by Frobenius reciprocity. The morphism $\text{ind}_H^G(\phi): \text{ind}_{\{1\}}^G(\mathbf{1}) \rightarrow \text{ind}_H^G(\chi)$ can be identified with the projection $F[G] \rightarrow F[G] / \sum_{h \in H} F[G](h - \chi(h))$. In particular, for $\chi = 1$, $\text{ind}_H^G(\mathbf{1}) \simeq F[G] / \sum_{h \in H} F[G](h - 1)$ is the permutation representation associated to the action of G on G/H .

Dually the identity map $\text{res}_{\{1\}}^H \chi \simeq \mathbf{1}$ induces by Frobenius reciprocity a morphism of representations $\psi: (F, \chi) \rightarrow \text{Ind}_{\{1\}}^H \chi$. Assume that H is finite. Identifying $\text{Ind}_{\{1\}}^H \chi$ with $F[H]$, we have $e_\chi := \psi(1) = \sum_{h \in H} \chi(h^{-1})h \in F[H]$. We have $\text{ind}_H^G(\chi) \simeq F[G]e_\chi$ carrying $g \otimes 1$ to ge_χ , and the morphism $\text{ind}_H^G(\psi): \text{ind}_H^G(\chi) \rightarrow \text{ind}_{\{1\}}^G(\mathbf{1})$ can be identified with the inclusion $F[G]e_\chi \hookrightarrow F[G]$. The composition $\text{ind}_H^G(\chi) \rightarrow F[G] \rightarrow \text{ind}_{\{1\}}^G(\mathbf{1})$ is multiplication by $\#H$.

Proposition 4.4.8. *Let W be an irreducible representation of G and V a subrepresentation (resp. quotient) of $\text{res}_H^G(W)$. Then W is a quotient of $\text{ind}_H^G(V)$ (resp. a subrepresentation of $\text{Ind}_H^G(V)$).*

¹In older literature, $\text{ind}_H^G(V)$ is called the induced representation and $\text{Ind}_H^G(V)$ the coinduced representation.

Proof. If V is a subrepresentation of $\text{res}_H^G(W)$, then, by Frobenius reciprocity, we have a nonzero homomorphism $\text{ind}_H^G(V) \rightarrow W$, which must be surjective by the irreducibility of W . On the other hand, if V is a quotient of $\text{res}_H^G(W)$, then, by Frobenius reciprocity, we have a nonzero homomorphism $W \rightarrow \text{Ind}_H^G(V)$, which must be an injection. \square

Corollary 4.4.9. *Assume that H is an abelian subgroup of G with $(G : H) = d < \infty$ and F is a splitting field for H . Then every finite-dimensional irreducible representation W of G over F has dimension $\leq d$.*

Proof. Let V be an irreducible subrepresentation of $\text{res}_H^G(W)$. Then $\dim_F V = 1$ by Corollary 4.2.4 and $\dim_F \text{ind}_H^G(V) = d$. By the proposition, W is a quotient of $\text{ind}_H^G(V)$, so that $\dim_F W \leq \dim_F \text{ind}_H^G(V) = d$. \square

We described the restrictions of the induced representations to $\{1\}$ in Remark 4.4.6. Next we describe the restriction of the induced representation to more general subgroups. It is convenient to introduce the following.

Notation 4.4.10. For $g \in G$, let $c_g: H^g := g^{-1}Hg \rightarrow H$ be the homomorphism given by $h \mapsto ghg^{-1}$. For a representation (V, ρ) of H , we let (V^g, ρ^g) denote $c_g^*(V, \rho)$.

Theorem 4.4.11 (Mackey). *Let H and K be subgroups of G and let (V, ρ) be a representation of H over F . Then we have isomorphisms of representations of K :*

$$\begin{aligned} \text{res}_K^G \text{Ind}_H^G(V) &\xrightarrow{\sim} \prod_{\bar{g} \in H \backslash G / K} \text{Ind}_{H^g \cap K}^K \text{res}_{H^g \cap K}^{H^g}(V^g), \\ \text{res}_K^G \text{ind}_H^G(V) &\xrightarrow{\sim} \bigoplus_{\bar{g} \in H \backslash G / K} \text{ind}_{H^g \cap K}^K \text{res}_{H^g \cap K}^{H^g}(V^g), \\ f &\mapsto (f_g), \end{aligned}$$

where $g \in G$ is any representative of the double coset \bar{g} , and $f_g: K \rightarrow V$ is given by $k \mapsto f(gk)$.

Proof. The inverse sends (f_g) to $f: G \rightarrow V$ with $f(hgk) = \rho(h)f_g(k)$ for $h \in H$, $K \in K$. \square

Remark 4.4.12. To a group G , we associate a category \mathbf{BG} with one object $*$ and with $\text{End}_{\mathbf{BG}}(*) = G$. The category $\mathbf{Rep}_F(G)$ can be identified with $\mathbf{Fun}(\mathbf{BG}, \mathbf{Vect}_F)$. For a homomorphism of groups $H \rightarrow G$, ϕ^* corresponds to composition with the functor $\mathbf{B}\phi: \mathbf{BH} \rightarrow \mathbf{BG}$. Moreover, $\phi_!$ and ϕ_* correspond respectively to left and right Kan extensions of functors in category theory.

For functors $F_1: \mathcal{C}_1 \rightarrow \mathcal{C}$ and $F_2: \mathcal{C}_2 \rightarrow \mathcal{C}$, we let $\mathcal{C}_1 \times_{\mathcal{C}}^h \mathcal{C}_2$ denote the *homotopy fiber product*: the objects are triples (X_1, X_2, α) , where X_i is an object of \mathcal{C}_i and $\alpha: F_1 X_1 \xrightarrow{\sim} F_2 X_2$ is an isomorphism in \mathcal{C} ; a morphism $(X_1, X_2, \alpha) \rightarrow (Y_1, Y_2, \beta)$ is a pair (f_1, f_2) with $f_i: X_i \rightarrow Y_i$ in \mathcal{C}_i such that $\beta F_1(f_1) = F_2(f_2)\alpha$. Then $\mathbf{BK} \times_{\mathbf{BG}}^h \mathbf{BH}$ is a *groupoid*, namely, a category in which all morphisms are isomorphisms. We have an equivalence of categories $\prod_{\bar{g} \in H \backslash G / K} \mathbf{B}(H^g \cap K) \rightarrow \mathbf{BK} \times_{\mathbf{BG}}^h \mathbf{BH}$ with the

component at \bar{g} carrying $*$ to $(*, *, g)$ and $k \in H^g \cap K$ to (k, gkg^{-1}) . Consider the square

$$\begin{array}{ccc} \mathbf{BK} \times_{\mathbf{BG}}^{\mathbf{h}} \mathbf{BH} & \xrightarrow{\psi'} & \mathbf{BH} \\ \phi' \downarrow & & \downarrow \phi \\ \mathbf{BK} & \xrightarrow{\psi} & \mathbf{BG}, \end{array}$$

commutative up to a natural isomorphism. We can rephrase Mackey's theorem in the following way: the natural transformations

$$\psi^* \phi_* \rightarrow \phi'_* \psi'^*, \quad \psi^* \phi_! \leftarrow \phi'_! \psi'^*,$$

induced from the natural isomorphism $\psi'^* \phi^* \simeq \phi'^* \psi^*$ by adjunction, are natural isomorphisms. Such statements about adjoint functors are sometimes referred to as the Beck–Chevalley condition.

Corollary 4.4.13. *Let H be a normal subgroup of G . Then*

$$\operatorname{res}_H^G \operatorname{Ind}_H^G(V) \simeq \prod_{\bar{g} \in G/H} V^g, \quad \operatorname{res}_H^G \operatorname{ind}_H^G(V) \simeq \bigoplus_{\bar{g} \in G/H} V^g.$$

Corollary 4.4.14. *Let G be a finite group with $\operatorname{char}(F) \nmid \#G$ and let H be a subgroup. Let V be an absolutely irreducible representation of H over F . Then $\operatorname{ind}_H^G(V)$ is absolutely irreducible if and only if for every $g \in G$, $g \notin H$, we have*

$$\operatorname{Hom}_{F[H^g \cap H]}(\operatorname{res}_{H^g \cap H}^{H^g}(V^g), \operatorname{res}_{H^g \cap H}^H(V)) = 0.$$

Proof. By Maschke's theorem and Theorem 4.2.3, $\operatorname{ind}_H^G(V)$ is absolutely irreducible if and only if $\operatorname{End}_{F[G]}(\operatorname{ind}_H^G(V)) = F$. By Frobenius reciprocity,

$$\begin{aligned} \operatorname{End}_{F[G]}(\operatorname{ind}_H^G(V)) &\simeq \operatorname{Hom}_{F[H]}(\operatorname{res}_H^G \operatorname{ind}_H^G(V), V) \\ &\simeq \operatorname{Hom}_{F[H]}(\bigoplus_{\bar{g} \in H \backslash G/H} \operatorname{ind}_{H^g \cap H}^H \operatorname{res}_{H^g \cap H}^{H^g}(V^g), V) \\ &\simeq \prod_{\bar{g} \in H \backslash G/H} \operatorname{Hom}_{F[H^g \cap H]}(\operatorname{res}_{H^g \cap H}^{H^g}(V^g), \operatorname{res}_{H^g \cap H}^H(V)), \end{aligned}$$

where we used Mackey's theorem. For $\bar{g} \in H \backslash G/H$, the factor is $\operatorname{End}_{F[H]}(V) = F$. Thus $\operatorname{End}_{F[G]}(\operatorname{ind}_H^G(V)) = F$ if and only if all the other factors are zero. \square

Proposition 4.4.15. *Let H be a subgroup of G of finite index and let (V, ρ) be a finite-dimensional representation of H over F . Then, for all $x \in G$,*

$$\chi_{\operatorname{ind}_H^G(V)}(x) = \sum_{\substack{\bar{g} \in H \backslash G \\ \bar{g} = \bar{g}x}} \chi_V(gxg^{-1}) = \sum_{\substack{\bar{g} \in G/H \\ x\bar{g} = \bar{g}}} \chi_V(g^{-1}xg),$$

where $g \in G$ is any representative of the coset \bar{g} .

Note that $\bar{g}x = \bar{g}$ if and only if $x \in H^g$. Moreover, $\chi_V(gxg^{-1}) = \chi_{V^g}(x)$. If x is not conjugate to an element of H , then $\chi_{\operatorname{ind}_H^G(V)}(x) = 0$.

Proof. We have an isomorphism

$$\mathrm{Ind}_H^G(V) \xrightarrow{\sim} \coprod_{\bar{g} \in H \backslash G} \mathrm{Map}_H(Hg, V),$$

where $\mathrm{Map}_H(Hg, V) := \{f: Hg \rightarrow V \mid f(hg) = \rho(h)f(g)\}$. Since x permutes the factors, we have

$$\chi_{\mathrm{Ind}_H^G(V)}(x) = \sum_{\substack{\bar{g} \in H \backslash G \\ \bar{g} = \bar{g}x}} \mathrm{tr}(x, \mathrm{Map}_H(Hg, V)).$$

Moreover, we have an isomorphism of H^g -representations

$$\mathrm{Map}_H(Hg, V) \xrightarrow{\sim} V^g \quad f \mapsto f(g).$$

Indeed, for $x \in H^g$, $(xf)(g) = f(gx) = f(gxg^{-1}g) = \rho(gxg^{-1})f(g)$. This finishes the proof of the first equality. The second one is obtained by taking $g \mapsto g^{-1}$. \square

Remark 4.4.16. Dually we can also prove the character formula using the tensor product description of $\mathrm{ind}_H^G(V)$. We have an isomorphism

$$F[G] \otimes_{F[H]} V \simeq \bigoplus_{\bar{g} \in G/H} \bar{g}F[H] \otimes_{F[H]} V.$$

Since x permutes the summands, we have

$$\chi_{\mathrm{ind}_H^G(V)} = \sum_{\substack{\bar{g} \in G/H \\ x\bar{g} = \bar{g}}} \mathrm{tr}(x, \bar{g}F[H] \otimes_{F[H]} V).$$

Finally, we have an isomorphism of gHg^{-1} -representations

$$V \xrightarrow{\sim} \bar{g}F[H] \otimes_{F[H]} V \quad v \mapsto g \otimes v.$$

Indeed, for $x \in gHg^{-1}$, we have $x(g \otimes v) = gg^{-1}xg \otimes v = g \otimes (g^{-1}xg)v$.

Definition 4.4.17. Let H be a subgroup of G of finite index. For a class function $\chi: H \rightarrow V$, we define the induced class function $\mathrm{ind}_H^G \chi: G \rightarrow V$ by $x \mapsto \sum_{\substack{\bar{g} \in G/H \\ x\bar{g} = \bar{g}}} \chi(g^{-1}xg)$.

The character formula for induced representations can be stated as $\chi_{\mathrm{ind}_H^G(V)} = \mathrm{ind}_H^G \chi$. We leave it to the reader to state and directly verify a version of Mackey's theorem for class functions.

Corollary 4.4.18. Let G be a finite group with $\mathrm{char}(F) \nmid \#G$ and let H be a subgroup of G . Let $\chi: H \rightarrow F$ and $\theta: G \rightarrow F$ be class functions. Then

$$\langle \theta, \mathrm{ind}_H^G \chi \rangle_G = \langle \mathrm{res}_H^G \theta, \chi \rangle_H.$$

Proof. Up to replacing F by an extension, we may assume that F is a splitting field for G and H . Then χ and θ are F -linear combinations of characters by Theorem 4.3.10 and we are reduced to the case of characters. We conclude by Frobenius reciprocity and Corollary 4.3.7. \square

Example 4.4.19. Let $G = A_4$, $H = V$. Assume $\text{char}(F) \neq 2, 3$ and let χ be a nontrivial character of $V \simeq (\mathbb{Z}/2\mathbb{Z})^2$ of dimension 1. Then $\text{ind}_V^{A_4}\chi$ equals the character θ of Example 4.3.15.

Example 4.4.20. Let $G = D_n$, $H = \langle r \rangle \simeq \mathbb{Z}/n\mathbb{Z}$. Assume $\text{char}(F) \nmid 2n$ and that F contains a primitive n -th root of unity ζ . Let ϕ_h be the character of $\langle r \rangle$ of dimension 1 given by $\phi_h(r^k) = \zeta^{hk}$. Then $\text{ind}_{\langle r \rangle}^{D_n}\phi_h$ equals the character χ_h of Example 4.3.16. We note however that χ_h is the character of a representation that can be realized over the smaller field $F_0(\zeta + \zeta^{-1})$, where F_0 denotes the prime field of F .

4.5 Representations of the symmetric group

Recall that any permutation $g \in \Sigma_n$ is a product of disjoint cycles. Up to adding cycles of length 1, we may assume that every integer in $1, \dots, n$ appears in one of the cycles. The *cycle type* of g is the collection of lengths of the cycles, which is a partition of n in the following sense.

Definition 4.5.1. A *partition* $\lambda = (\lambda_1 \geq \dots \geq \lambda_r)$ of n is a collection of positive integers such that $\lambda_1 + \dots + \lambda_r = n$. In this case, we write $\lambda \vdash n$.

Two permutations are conjugate in Σ_n if and only if they have the same cycle type. Thus the conjugacy classes of Σ_n are in bijection with partitions of n .

A partition $\lambda = (\lambda_1 \geq \dots \geq \lambda_r)$ can be visualized as a *Young diagram* with λ_i boxes on the i -th row. For example, the Young diagram of $\lambda = (3 \geq 2)$ is²

$$(4.5.1) \quad \begin{array}{|c|c|c|} \hline \square & \square & \square \\ \hline \square & \square & \\ \hline \end{array}$$

A *Young tableau* of shape $\lambda \vdash n$ is the Young diagram corresponding to λ , with $1, \dots, n$ filled in without repetition. For example the Young diagram (4.5.1) can be filled into the Young tableau

$$(4.5.2) \quad \begin{array}{|c|c|c|} \hline 4 & 5 & 2 \\ \hline 3 & 1 & \\ \hline \end{array}$$

The group Σ_n acts freely and transitively on the set of Young tableaux of shape $\lambda \vdash n$ by permuting the integers.

Two Young tableaux t and t' are said to be *row equivalent* if for each i , the i -th row of t and the i -th row of t' have the same set of integers. The row stabilizer subgroup of t is $R_t < \Sigma_n$ consisting of elements $g \in \Sigma_t$ such that t and gt are row equivalent. Similarly, we can define column equivalence and column stabilizers. The latter is denoted by C_t . For the Young tableau t in (4.5.2), $R_t = \Sigma_{\{2,4,5\}} \times \Sigma_{\{1,3\}}$ and $C_t = \Sigma_{\{3,4\}} \times \Sigma_{\{1,5\}}$.

Let F be a field.

²We adopt the English notation. In the French notation, the diagram is upside down: $\begin{array}{|c|c|c|} \hline \square & \square & \\ \hline \square & \square & \square \\ \hline \end{array}$.

Definition 4.5.2. For a Young tableau t , we define the *Specht module* S^t to be the image of the canonical morphism (Example 4.4.7)

$$\mathrm{ind}_{C_t}^{\Sigma_n}(\mathrm{sgn}) \rightarrow F[\Sigma_n] \rightarrow \mathrm{ind}_{R_t}^{\Sigma_n}(\mathbf{1})$$

of representations of Σ_n over F .

Remark 4.5.3. Unwinding the definition, S^t can be identified with $F[\Sigma_n]c_t$, where $c_t = e_{\mathrm{sgn}|_{C_t}}e_{\mathbf{1}_{R_t}} = \sum_{g \in R_t} \sum_{h \in C_t} \mathrm{sgn}(h)hg \in F[G]$. This element is called the *Young symmetrizer*.

For t of shape (n) , $c_t = \sum_{g \in \Sigma_n} g$ and for t of shape $(1 \geq \dots \geq 1)$, $c_t = \sum_{g \in \Sigma_n} \mathrm{sgn}(g)g$. For any F -vector space V , we discussed the effects of these two symmetrizers on the representation $V^{\otimes n}$ of Σ_n above Proposition 3.1.20.

Theorem 4.5.4. Assume that $\mathrm{char}(F) \nmid n!$. Then each S^t is absolutely irreducible and every irreducible representation of Σ_n over F is isomorphic to some S^t . Moreover, $S^t \simeq S^{t'}$ if and only if t and t' have the same shape. In particular, $\mathrm{shape}(t) \mapsto [S^t]$ gives a one-one correspondence between partitions of n and isomorphism classes of representations of Σ_n over F .

Corollary 4.5.5. Σ_n splits over any field of characteristic $\nmid n!$.

It is convenient to define a canonical representative of the isomorphism class corresponding to a partition λ as follows. A row equivalence class of Young tableaux is called a *tabloid*. We denote the tabloid containing a tableau t by $\{t\}$ and we visualize it by removing the vertical edges in the tableau. For example, for the tableau t in (4.5.2), the tabloid $\{t\}$ is visualized as

$$\begin{array}{ccc} \hline 4 & 5 & 2 \\ \hline 3 & 1 & \\ \hline \end{array}$$

The group Σ_n acts transitively on the set of Young tabloids of shape $\lambda \vdash n$ by $g\{t\} = \{gt\}$, with R_t being the stabilizer of $\{t\}$. We let M^λ denote the corresponding permutation representation. We have an isomorphism

$$(4.5.3) \quad \mathrm{ind}_{R_t}^{\Sigma_n}(\mathbf{1}) \xrightarrow{\sim} M^\lambda, \quad g \otimes 1 \mapsto g\{t\}.$$

We define $e_t := e_{\mathrm{sgn}|_{C_t}} = \sum_{h \in C_t} \mathrm{sgn}(h)h \in F[\Sigma_n]$, $v_t = e_t\{t\} \in M^\lambda$ for t of shape λ , and $S^\lambda = \sum_{\mathrm{shape}(t)=\lambda} Fv_t$.

Lemma 4.5.6. For every $g \in G$, we have

$$R_{gt} = gR_tg^{-1}, \quad C_{gt} = gC_tg^{-1}, \quad e_{gt} = ge_tg^{-1}, \quad v_{gt} = gv_t.$$

Proof. The first (resp. second) equality follow from the fact that ht is row (resp. column) equivalent to t if and only if $ght = (ghg^{-1})(gt)$ is row (resp. column) equivalent to gt . It follows that $e_{gt} = \sum_{h \in C_t} \mathrm{sgn}(g^{-1}hg)g^{-1}hg = e_t$. Finally, $v_{gt} = ge_tg^{-1}\{gt\} = gv_t$. \square

It follows that for any t of shape λ , $S^\lambda = \sum_{g \in G} Fv_{gt} = F[G]v_t$.

Proposition 4.5.7. *The isomorphism (4.5.3) induces an isomorphism $S^t \xrightarrow{\simeq} S^\lambda$.*

We call S^λ the Specht module of shape λ .

Proof. By Example 4.4.7, $S^t = F[G](e_t \otimes 1)$. Thus the image of S^t under (4.5.3) is $F[G]v_t = S^\lambda$. \square

Example 4.5.8. For $\lambda = (n)$, $S^\lambda = M^\lambda = \mathbf{1}$. For $\lambda = (1 \geq \dots \geq 1)$, M^λ is the regular representation, $C_t = \Sigma_n$ for any tableau t of shape λ , and $S^\lambda = \text{sgn}$.

For $\lambda = (n - 1 \geq 1)$, we have a bijection from the set of tabloids of shape λ to $\{1, \dots, n\}$ carrying $\{t\}$ to its value on the second row. We denote the Young tabloid mapping to i by m_i . Then $M^\lambda = \bigoplus_{i=1}^n Fm_i$ with obvious action of Σ_n , and S^λ is spanned by $m_i - m_j$. In other words, S^λ can be identified with $\ker(F^n \xrightarrow{\Sigma} F)$, which is called the *standard representation* of Σ_n and denoted by std if $\text{char}(F) \nmid n!$. Note that $\chi_{M^\lambda}(g)$ equals the number of fixed points of g on $\{1, \dots, n\}$, and $\chi_{S^\lambda}(g) = \chi_{M^\lambda}(g) - 1$.

In general, $\chi_{M^\lambda}(g)$ is the number Young tabloids of shape λ fixed by g .

Remark 4.5.9. If $\lambda \vdash n$ and λ' denotes the *transpose* (or *conjugate*) partition of λ corresponding to the transposed Young diagram, then $S^{\lambda'} \simeq \text{sgn} \otimes (S^\lambda)^\vee$. Indeed, for any finite group G and $c = \sum_{g \in G} a_g g \in F[G]$, we have a commutative diagram

$$\begin{array}{ccc} F[G] & \xrightarrow{\phi_{c^*}} & F[G] \\ f \downarrow \simeq & & \simeq \downarrow f \\ F[G]^\vee & \xrightarrow{\phi_c^\vee} & F[G]^\vee, \end{array}$$

where $f(g) = g^\vee$, $(g^\vee)_{g \in G}$ is a dual basis of G , $c^* = \sum_{g \in G} a_g g^{-1}$, and ϕ_c is right multiplication by c . Thus $\text{im}(\phi_{c^*}) \simeq \text{im}(\phi_c^\vee)$. Moreover, for $G = \Sigma_n$, $\text{im}(\phi_{c^-}) \simeq \text{sgn} \otimes \text{im}(\phi_c)$, where $c^- = \sum_{g \in \Sigma_n} \text{sgn}(g) a_g g$. If t is a tableau and t' denotes its transpose, then $c^{t'} = (c_t^*)^-$.

Since every $g \in \Sigma_n$ is conjugate to g^{-1} , we have $(S^\lambda)^\vee \simeq S^\lambda$ if $\text{char}(F) \nmid n!$ (exercise).

Example 4.5.10. Here is the character table of Σ_4 (assuming $\text{char}(F) \neq 2, 3$).

g	e	(12)	(123)	(1234)	(12)(34)
$\#C_g$	1	6	8	6	3
$\mathbf{1}$	1	1	1	1	1
sgn	1	-1	1	-1	1
χ_{std}	3	1	0	-1	-1
$\text{sgn} \cdot \chi_{\text{std}}$	3	-1	0	1	-1
χ	2	0	-1	0	2

Here χ is obtained by inflation from the standard representation of Σ_3 via $\Sigma_4 \rightarrow \Sigma_4/V \simeq \Sigma_3$.

We will first prove the absolute irreducibility of S^λ .

Lemma 4.5.11. *Let t be a tableau with n boxes. For every transposition $h \in C_t$, $e_t \in F[\Sigma_n](1 - h)$. If $h \in C_t \cap R_s$ is a transposition for a tableau s with n boxes, then $e_t\{s\} = 0$.*

Proof. Let (h_i) be a system of representatives of $C_t/\langle h \rangle$. Then

$$e_t = \sum_i \operatorname{sgn}(h_i)h_i - \sum_i \operatorname{sgn}(h_i)h_i h = \sum_i \operatorname{sgn}(h_i)h_i(1 - h).$$

For $h \in R_s$, $(1 - h)\{s\} = 0$. □

Lemma 4.5.12. *Let t be a tableau of shape λ . Then $e_t M^\lambda = Fv_t$. Moreover, if s is a tableau of shape λ satisfying $e_t\{s\} \neq 0$, then $e_t\{s\} = \pm v_t$.*

Proof. By the previous lemma, the integers in the first row of s lie in different columns of t . Thus there exists $h \in C_t$ that carries these integers to the first row of t . Then the first rows of $\{ht\}$ and $\{s\}$ coincides. Proceeding row by row, we can find $g \in C_t$ such that $g\{t\} = \{s\}$. Then

$$e_t\{s\} = \sum_{h \in C_t} \operatorname{sgn}(h)hg\{t\} = \operatorname{sgn}(g)e_t\{t\} = \pm v_t.$$

This implies $e_t M^\lambda \subseteq Fv_t$. The inclusion in the other direction is trivial: $e_t\{t\} = v_t$. □

Proposition 4.5.13. *Let $\lambda \vdash n$. Then $\operatorname{Hom}_{F[\Sigma_n]}(S^\lambda, M^\lambda) = F \cdot \operatorname{id}$.*

Proof. Let t be a tableau of shape λ . For any $\phi \in \operatorname{Hom}_{F[\Sigma_n]}(S^\lambda, M^\lambda)$, $\phi(v_t) = e_t\phi(\{t\}) = cv_t$ for some $c \in F$ by the previous lemma. We conclude by the fact that $S^\lambda = F[\Sigma_n]v_t$. □

Corollary 4.5.14. *Assume $\operatorname{char}(F) \nmid n!$. Then S^λ is absolutely irreducible.*

Proof. We have $\operatorname{End}_{F[\Sigma_n]}(S^\lambda) \subseteq \operatorname{Hom}_{F[\Sigma_n]}(S^\lambda, M^\lambda) = F \cdot \operatorname{id}$, and thus is either $F \cdot \operatorname{id}$ or 0. It remains to show that S^λ is nonzero. Let t be a tableau of shape λ such that for every $i < j$, the integers on the i -th row are all smaller than the integers on the j -th row. Then the only element $h \in C_t$ satisfying $h\{t\} = \{t\}$ is $h = e$. It follows that the coefficient of $\{t\}$ in v_t is 1. In particular, $0 \neq v_t \in S^\lambda$. □

To finish the proof of the theorem, we need a bit more combinatorial preliminaries.

Definition 4.5.15. For $\lambda, \mu \vdash n$ with $\lambda = (\lambda_1 \geq \dots \geq \lambda_r)$ and $\mu = (\mu_1 \geq \dots \geq \mu_s)$, we say that λ *dominates* μ and we write $\lambda \triangleright \mu$, if $\sum_{i=1}^k \lambda_i \geq \sum_{i=1}^k \mu_i$ for all $k \geq 1$. Here we convene that $\lambda_i = 0$ for $i > r$ and $\mu_i = 0$ for $i > s$.

The dominance relation on partitions of n is a partial order. There is no dominance between $(4 \geq 1 \geq 1)$ and $(3 \geq 3)$.

Lemma 4.5.16. *Let $\lambda, \mu \vdash n$ and let t and s be tableaux of shapes λ and μ , respectively. Assume that the integers in each row of s lie in different columns of t . Then $\lambda \triangleright \mu$.*

Proof. The first row of s has μ_1 integers, which are in different columns of t . Up to replacing t by ht with $h \in C_t$, we may assume that these numbers are in the first row of t . Thus $\lambda_1 \geq \mu_1$.

The second row of s has μ_2 integers, which are in different columns of t . Up to replacing t by ht with $h \in C_t$, we may assume, without modifying the integers of the previous step, that these integers are in the first two rows of t . Then $\lambda_1 + \lambda_2 \geq \mu_1 + \mu_2$. We continue in this way and conclude by induction. \square

It follows from Lemmas 4.5.11 and 4.5.16 that if $e_t M^\mu \neq 0$, then $\lambda \triangleright \mu$.

Proposition 4.5.17. *Let $\lambda, \mu \vdash n$ such that $\text{Hom}_{F[\Sigma_n]}(S^\lambda, M^\mu) \neq 0$. Then $\lambda \triangleright \mu$.*

Proof. Let $\phi \in \text{Hom}_{F[\Sigma_n]}(S^\lambda, M^\mu)$. For every tableau of shape λ , $\phi(v_t) = e_t \phi(\{t\})$, which is zero unless $\lambda \triangleright \mu$. \square

Proof of Theorem 4.5.4. We have already seen that S^λ is absolutely irreducible. Assume $S^\lambda \simeq S^\mu$. Then $\text{Hom}_{F[\Sigma_n]}(S^\lambda, M^\mu) \neq 0$. By the proposition, $\lambda \triangleright \mu$. By symmetry, $\mu \triangleright \lambda$. Thus $\mu = \lambda$.

It follows that the S^λ represent $p(n)$ isomorphism classes of irreducible representations, where $p(n)$ denotes the number of partitions of n . The number of isomorphism classes of irreducible representations is less than or equal to the number of conjugacy classes, which equals $p(n)$. Thus the S^λ exhaust all isomorphism classes of irreducible representations. \square

In the rest of this section we assume $\text{char}(F) \nmid n!$.

Corollary 4.5.18. *Let $\mu \vdash n$. Then $M^\mu \simeq \bigoplus_{\lambda \triangleright \mu} (S^\lambda)^{\oplus m_{\lambda, \mu}}$ with $m_{\mu, \mu} = 1$.*

Proof. We have $M^\mu \simeq \bigoplus_{\lambda \vdash n} (S^\lambda)^{\oplus m_{\lambda, \mu}}$. By Proposition 4.5.17, $m_{\lambda, \mu} = 0$ unless $\lambda \triangleright \mu$. Moreover, $m_{\mu, \mu} = 1$ by Proposition 4.5.13. \square

Young's rule says that $m_{\lambda, \mu}$ equals the *Kostka number*, the number of semistandard tableaux of shape λ and type μ . Given $\lambda, \mu \vdash n$, a *generalized tableau of shape λ and type μ* is the Young diagram for λ filled with integers, with the integer i repeated μ_i times.³ A *semistandard tableau* of type μ is a generalized tableau of which each row is nondecreasing and each column is increasing.

For $\mu = (1 \geq \cdots \geq 1)$, M^μ is the regular representation and $\dim_F S^\lambda = m_{\lambda, \mu}$ is the number of standard Young tableaux of shape λ . A *standard Young tableau* is a Young tableau with increasing rows and columns, namely a semistandard tableau of type $(1 \geq \cdots \geq 1)$. In fact, v_λ , λ running through standard Young tableaux of shape λ , form an F -linear basis of S^λ . Another description of the dimension of S^λ is the *hook length formula* (Frame–Robinson–Thrall):

$$\dim_F S^\lambda = \frac{n!}{\prod_x h(x)},$$

where x runs through boxes of the Young diagram for λ and $h(x)$ denotes the length of the hook with corner x , namely the number of boxes directly below or directly to the right of x , including x itself.

We refer to [S1] for a proof of these facts and more on the symmetric group.

³A Young tableau is a generalized tableau of type $(1 \geq \cdots \geq 1)$.

Example 4.5.19. Here is the character table of Σ_5 (assuming $\text{char}(F) \neq 2, 3, 5$).

	g	e	(12)	(123)	(1234)	(12345)	(12)(34)	(123)(45)
	$\#C_g$	1	10	20	30	24	15	20
$\mathbb{1}$	$\mathbf{1}$	1	1	1	1	1	1	1
$\begin{array}{ c } \hline \square \\ \hline \end{array}$	sgn	1	-1	1	-1	1	1	-1
$\begin{array}{ c c } \hline \square & \square \\ \hline \end{array}$	χ_{std}	4	2	1	0	-1	0	-1
$\begin{array}{ c c } \hline \square & \square \\ \hline \end{array}$	$\text{sgn} \cdot \chi_{\text{std}}$	4	-2	1	0	-1	0	1
$\begin{array}{ c c c } \hline \square & \square & \square \\ \hline \end{array}$	$\chi_{\wedge^2 \text{std}}$	6	0	0	0	1	-2	0
$\begin{array}{ c c } \hline \square & \square \\ \hline \end{array}$	χ_V	5	1	-1	-1	0	1	1
$\begin{array}{ c c } \hline \square & \square \\ \hline \end{array}$	$\text{sgn} \cdot \chi_V$	5	-1	-1	1	0	1	-1

To obtain the last three lines, we use the formulas (exercise)

$$\chi_{\text{Sym}^2 V}(g) = \frac{\chi_V(g)^2 + \chi_V(g^2)}{2}, \quad \chi_{\wedge^2 V}(g) = \frac{\chi_V(g)^2 - \chi_V(g^2)}{2}.$$

to compute $\chi_{\wedge^2 \text{std}}$ and $\chi_{\text{Sym}^2 \text{std}} = (10, 4, 1, 0, 0, 2, 1)$. Then

$$\langle \chi_{\wedge^2 \text{std}}, \chi_{\wedge^2 \text{std}} \rangle = 1, \quad \langle \chi_{\text{Sym}^2 \text{std}}, \chi_{\text{Sym}^2 \text{std}} \rangle = 3, \quad \langle \chi_{\text{Sym}^2 \text{std}}, \mathbf{1} \rangle = 1, \quad \langle \chi_{\text{Sym}^2 \text{std}}, \text{std} \rangle = 1.$$

Thus $\text{Sym}^2 \text{std} \simeq \mathbf{1} \oplus \text{std} \oplus V$ for a representation V of dimension 5. The character $\chi_V = \chi_{\text{Sym}^2 \text{std}} - \mathbf{1} - \chi_{\text{std}}$ satisfies $\langle \chi_V, \chi_V \rangle = 1$. Let us check that $\wedge^2 \text{std}$ and V are irreducible representations. This is clear if $\text{char}(F) = 0$. For $\text{char}(F) = p$, writing $V \simeq \bigoplus_i V_i^{\oplus m_i}$ with V_i irreducible, we get $\sum_i m_i n_i = 5$ and $\sum_i m_i^2 \equiv 1 \pmod{p}$, where $n_i = \dim_F V_i$. The only solution is $m_i = 1$ for exactly one i and $m_i = 0$ for all other i . For $\wedge^2 \text{std}$, note that the only representations of dimension 1 are $\mathbf{1}$ and sgn (which follows for example from the fact the Jordan–Hölder factors of Σ_5 are A_5 and $\mathbb{Z}/2\mathbb{Z}$), and $\langle \chi_{\wedge^2 \text{std}}, \mathbf{1} \rangle = \langle \chi_{\wedge^2 \text{std}}, \text{sgn} \rangle = 0$. It follows that $\wedge^2 \text{std} \simeq \bigoplus_i V_i^{m'_i}$ with V_i irreducible and $n_i = \dim_F V_i \geq 2$. Then $\sum_i m'_i n_i = 6$ and $\sum_i m_i'^2 \equiv 1 \pmod{p}$, and the only solution is $m'_i = 1$ for exactly one i and $m'_i = 0$ for all other i .

Since $\chi_{\wedge^2 \text{std}} = \text{sgn} \cdot \chi_{\wedge^2 \text{std}}$, it is the character of S^λ for the only partition $\lambda = (3 \geq 1 \geq 1) \vdash 5$ satisfying $\lambda' = \lambda$. Finally, we need to identify $\chi_{S(3 \geq 2)}$ and $\chi_{S(2 \geq 2 \geq 1)}$. One checks that $\chi_{M(3 \geq 2)}$ equals $\chi_{\text{Sym}^2 \text{std}}$. Indeed, the Young tabloids of shape $(3 \geq 2)$

fixed by g are as follows.

e	(12)	(123)	(1234)	(12345)	(12)(34)	(123)(45)	
all 10	$\begin{array}{ c c c } \hline 1 & 2 & 3 \\ \hline 4 & 5 & \\ \hline \end{array}$	$\begin{array}{ c c c } \hline 1 & 2 & 3 \\ \hline 4 & 5 & \\ \hline \end{array}$	(none)	(none)		$\begin{array}{ c c c } \hline 1 & 2 & 3 \\ \hline 4 & 5 & \\ \hline \end{array}$	
	$\begin{array}{ c c c } \hline 1 & 2 & 4 \\ \hline 3 & 5 & \\ \hline \end{array}$						
	$\begin{array}{ c c c } \hline 1 & 2 & 5 \\ \hline 3 & 4 & \\ \hline \end{array}$					$\begin{array}{ c c c } \hline 1 & 2 & 5 \\ \hline 3 & 4 & \\ \hline \end{array}$	
	$\begin{array}{ c c c } \hline 3 & 4 & 5 \\ \hline 1 & 2 & \\ \hline \end{array}$					$\begin{array}{ c c c } \hline 3 & 4 & 5 \\ \hline 1 & 2 & \\ \hline \end{array}$	

Then $\chi_{M(3 \geq 2)} = \mathbf{1} + \chi_{\text{std}} + \chi$. It follows that $\chi_{S(3 \geq 2)} = \chi_V$ and $\chi_{S(2 \geq 2 \geq 1)} = \text{sgn} \cdot \chi_V$.

Consider $V = M^{n-1 \geq 1} = \bigoplus_{i=1}^n Fm_i = \mathbf{1} \oplus \text{std}$ and $V^{\otimes n}$ (where Σ_n acts on each copy of V but does not permute the copies). Then $V^{\otimes n}$ contains the regular representation of Σ_n . Indeed, the map $F[G] \rightarrow V^{\otimes n}$ given by $a \mapsto a(m_1 \otimes \cdots \otimes m_n)$ is injective. It follows that every irreducible representation of Σ_n is a factor of $\text{std}^{\otimes k}$ for some $0 \leq k \leq n$.

One can show that $S^{(n-k \geq 1 \geq \cdots \geq 1)} \simeq \wedge^k \text{std}$.

There are several other approaches to the representation theory of the symmetric group, of which we mention the recent one of Vershik and Okounkov based on the chain $\Sigma_1 < \cdots < \Sigma_{n-1} < \Sigma_n$ [VO].

4.6 Induction theorems

Definition 4.6.1. We say that a group G is *supersolvable* if there exists an ascending chain of subgroups $\{1\} = G_0 < \cdots < G_n = G$ of normal subgroups of G such that G_i/G_{i-1} is cyclic for all $1 \leq i \leq n$. We say that a group G is *nilpotent* if there exists a finite central series: an ascending chain of subgroups $\{1\} = G_0 < \cdots < G_n = G$ of normal subgroups of G such that $G_i/G_{i-1} \subseteq Z(G/G_{i-1})$ for all $1 \leq i \leq n$.

Remark 4.6.2. (1) A supersolvable group is clearly solvable.

(2) A central extension of a supersolvable group by a finite abelian group is supersolvable. It follows that a finite nilpotent group is supersolvable.

Example 4.6.3. (1) Any abelian group is nilpotent.

(2) Any p -group is nilpotent. For this, it suffices to show that for every nontrivial p -group G has nontrivial center. Consider the conjugation action of G on G . The cardinality of each orbit is a power of p . Thus the cardinality of the fixed point set $Z(G)$ is congruent to $\#G$ modulo p . In other words, $p \mid \#Z(G)$.

- (3) D_n is supersolvable: $\langle r \rangle < D_n$. However, D_3 is not nilpotent: $Z(D_3) = \{1\}$.
- (4) A_4 is solvable but not supersolvable.

Theorem 4.6.4. *Let G be a finite supersolvable group. Let F be a field $\text{char}(F) \neq \#G$, splitting all subgroups of G . Then every irreducible representation of G over F is induced from a 1-dimensional representation of some subgroup.*

Lemma 4.6.5. *Let G be a nonabelian supersolvable group. There exists a normal abelian subgroup N of G such that $N \supsetneq Z(G)$.*

Proof. The quotient $\bar{G} = G/Z(G)$ is supersolvable. Let $1 = \bar{G}_0 \leq \dots \leq \bar{G}_n = \bar{G}$ be a sequence of normal subgroups of \bar{G} with \bar{G}_i/\bar{G}_{i-1} cyclic for all i . In particular, $\bar{G}_1 = \langle g \rangle$ is cyclic. Then it suffices to take N to be the inverse image of \bar{G}_1 in G . Note that N is abelian since it is generated by $Z(G)$ and any $g \in G$ of image \bar{g} . \square

Lemma 4.6.6 (Clifford). *Let G be a group and $N \triangleleft G$ a normal subgroup. Let (V, ρ) be an irreducible representation of G over F . Then*

$$\text{res}_N^G(V) \simeq \bigoplus_{i \in I} (W_i)^{\oplus J},$$

where the W_i are irreducible representations of N satisfying $W_i \not\cong W_{i'}$ for $i \neq i'$. Moreover, for every $i \in I$, we have $V \simeq \text{ind}_{H_i}^G(W_i^{\oplus J})$, where $H_i < G$ is the stabilizer of $W_i^{\oplus J}$, and $(G : H_i) = \#I$.

Proof. Choose an irreducible subrepresentation W of $\text{res}_N^G(V)$. Since V is irreducible, we have $\text{res}_N^G(V) = \sum_{\bar{g} \in G/N} \rho(g)W$. We have $\rho(g)W \simeq W^{g^{-1}}$. Let $H = \{g \in G \mid W^{g^{-1}} \simeq W\}$. Then $W' := \sum_{\bar{h} \in H/N} \rho(h)W \simeq W^{\oplus J}$ for some J . Moreover,

$$\text{res}_N^G(V) = \sum_{\bar{g} \in G/H} \rho(g)W' \simeq \sum_{\bar{g} \in G/H} (W^{\oplus m})^{g^{-1}}.$$

The sum is a direct sum decomposition into isotypic components. Thus G permutes the isotypic components and H is the stabilizer of $W^{\oplus J}$. Finally, we have

$$\text{ind}_H^G(W') = F[G] \otimes_{F[H]} W' \xrightarrow{\sim} \bigoplus_{\bar{g} \in G/H} \rho(g)W' = V$$

given by $g \otimes v \mapsto \rho(g)v$. \square

Remark 4.6.7. Let $\phi: G \rightarrow \bar{G}$ be a surjective homomorphism, $\bar{H} < \bar{G}$ a subgroup and $H = \phi^{-1}(\bar{H})$. For any representation V of \bar{G} , composition with ϕ induces $\phi^* \text{Ind}_{\bar{H}}^{\bar{G}} V \xrightarrow{\sim} \text{Ind}_H^G(\phi_H^* V)$, where $\phi_H: H \rightarrow \bar{H}$ is the restriction of ϕ .

Proof of Theorem 4.6.4. We proceed by induction on $\#G$. Let (V, ρ) be an irreducible representation of G . Then (V, ρ) is the inflation of a representation of $\bar{G} = G/\ker(\rho)$. By the previous remark, we may assume that (V, ρ) is a *faithful* representation⁴, namely that $\ker(\rho) = 1$. If G is abelian, then F splits G and

⁴A faithful $F[G]$ -module is a faithful representation of G over F , but the converse does not hold in general.

$\dim_F V = 1$ by Corollary 4.2.4. Otherwise, by Lemma 4.6.5, there exists a normal abelian subgroup $N \triangleleft G$ that is not contained in $Z(G)$. We apply Lemma 4.6.6. Since F splits N , we have $\dim_F W_i = 1$. If $n = 1$, then every $g \in N$ acts by scalar multiplication by $\chi_{W_1}(g)$ on V , so that $\rho(N) \subseteq Z(\rho(G))$, which contradicts the assumption that N is not contained in $Z(G)$. Thus $H \subsetneq G$ and $V \simeq \text{ind}_H^G(W)$, where W is a representation of H . Since V is irreducible, so is W . We conclude by induction hypothesis. \square

Remark 4.6.8. The assumption that F splits subgroups of G cannot be dropped. For example, for $G = \mathbb{Z}/3\mathbb{Z}$, the simple $\mathbb{R}[G]$ -module of dimension 2 is not induced from a representation of dimension 1.

A representation induced from a 1-dimensional representation is called *monomial*. A finite group such that all irreducible representations over \mathbb{C} are monomial is called an *M-group* (or *monomial group*). Thus supersolvable groups are M-groups. Taketa showed that M-groups are solvable.

Example 4.6.9. (1) We have seen that A_4 is an M-group, but not supersolvable.

(2) Let $G < \mathbb{H}^\times$ be the union of $H = \{\pm 1, \pm i, \pm j, \pm k\}$ and the 16 elements $\frac{\pm 1 \pm i \pm j \pm k}{2}$. Then H is solvable: $\{1\} < \{\pm 1\} < H < G$ is a composition series. However, G is not an M-group. The map $G \rightarrow \mathbb{H} \otimes_{\mathbb{R}} \mathbb{C} \simeq M_2(\mathbb{C})$ carrying g to $g \otimes 1$ gives a 2-dimensional representation of G over \mathbb{C} , which is not monomial, because G has no subgroup of order 2. (As a side note, $G \simeq \text{SL}_2(\mathbb{F}_3) := \ker(\det: \text{GL}_2(\mathbb{F}_3) \rightarrow \mathbb{F}_3^\times)$.)

Definition 4.6.10. For a prime number p , a product of a p -group with a cyclic group of order prime to p is called a *p-elementary group*. A group is said to be *elementary* if it is p -elementary for some prime p .

Elementary groups are clearly supersolvable.

Theorem 4.6.11. Let G be a finite group and F a field with $\text{char}(F) = 0$.

- (1) (Artin) Every character χ of G is a \mathbb{Q} -linear combination of characters induced from characters of cyclic subgroups. More precisely, there are integers $a_H \in \mathbb{Z}$ such that $\chi = \sum_H \frac{a_H}{(N_G(H):H)} \text{ind}_H^G(\mathbf{1})$, where H runs through cyclic subgroups of G .
- (2) (Brauer) Assume that F splits G . Then every character of G is a \mathbb{Z} -linear combination of characters induced from characters of elementary subgroups. In particular, every character of G is a \mathbb{Z} -linear combination of monomial characters.

For a proof we refer to [S2, §§9, 10] and [J, §5.12].

Brauer's theorem is very useful in reducing problems about representations to the special case of 1-dimensional representations. Brauer used it to prove that Artin L -functions are meromorphic. Here is another application.

Corollary 4.6.12. Let G be a finite group of exponent m and let F be a field with $\text{char}(F) = 0$ and containing a primitive m -th root of unity. Then F is a splitting field of G .

Proof. Let K/F be a splitting field of G . By Corollary 4.3.4, it suffices to show that every representation W of G over K can be realized over F . By Brauer's theorem, $\chi_W = \sum_{i=1}^n a_i \text{ind}_{H_i}^G(\lambda_i)$, where for each i , $a_i \in \mathbb{Z}$, $H_i < G$ is a subgroup and $\lambda_i: H_i \rightarrow K$ is a character of dimension 1. For every $g \in H_i$, $\lambda_i(g)^m = \lambda_i(g^m) = 1$, so that $\lambda_i(g) \in F$. Note that $\text{ind}_{H_i}^G(F, \lambda_i)$ is a representation of G over F . It follows that $\chi_W = \sum_{i=1}^r c_i \chi_{V_i}$, where $c_i \in \mathbb{Z}$ and V_1, \dots, V_r are irreducible representations of G over F with $V_i \not\cong V_j$ for $i \neq j$. Then $(V_i)_K$ and $(V_j)_K$ have no common irreducible factor. It follows that $W \simeq (V_i)_K$ for some i . \square

Corollary 4.6.13. *Let G be a finite group of exponent m and let F be a field with $\text{char}(F) = 0$. Let V be an irreducible representation of G over F and let $D = \text{End}_{F[G]}(V)$. Let $t = [Z(D) : F]$ and $d^2 = \dim_{Z(D)}(D)$. Then $td \mid \varphi(m)$, where φ is Euler's totient function.*

Proof. Let ζ_m be a primitive m -th root of unity. Then $F(\zeta_m)$ is a splitting field of G . By Proposition 4.3.2, $td \mid [F(\zeta_m) : F] \mid \varphi(m)$. \square

We end this section with some miscellaneous results. Given a field extension K and a function $\chi: G \rightarrow K$, we let $F(\chi)$ denote the subfield of K generated by F and $\chi(g)$, $g \in G$.

Proposition 4.6.14. *Let G be a finite group and F a field with $\text{char}(F) \nmid \#G$. Let K/F be an extension splitting G . Let V be an irreducible representation of G and let W be an irreducible factor of V_K . Let $D = \text{End}_{F[G]}(V)$. Then there exists an F -isomorphism $Z(D) \simeq F(\chi_W)$.*

For a representation (W, π) over a field K and $\sigma \in \text{Aut}(K)$, we let (W^σ, π^σ) denote the representation of G over K where W^σ is W equipped with the structure of K -vector space given by $c \cdot_{W^\sigma} w = \sigma(c) \cdot_W w$, for $c \in K$ and $w \in W$. If $\sigma: K[G] \rightarrow K[G]$ denotes the ring homomorphism induced by σ , we have $W^\sigma = \sigma^*W$ as $F[G]$ -module. Under a chosen K -linear basis of W , $\pi^\sigma(g)$ is obtained from $\pi(g)$ by applying σ^{-1} . It follows that $\chi_{W^\sigma} = \sigma^{-1}\chi_W$.

Proof. We may assume that K/F is a finite Galois extension of group Γ . We have $D \otimes_F K \simeq \prod_\iota D \otimes_{Z(D)} K$, where ι runs through F -embeddings $Z(D) \rightarrow K$. The factors correspond to isomorphism classes of irreducible factors of V_K , with compatible action of Γ . Let ι be the embedding corresponding to W . Let H be the stabilizer of ι , which is also the stabilizer of χ_W . Then $\iota(Z(D)) = K^H$. Moreover, $\sigma \in \Gamma$ stabilizes χ_W if and only if σ fixes $F(\chi_W)$. Thus $F(\chi_W) = K^H$. \square

Proposition 4.6.15. *Let G be a finite group and let F be a field of characteristic $p > 0$ satisfying $p \nmid \#G$.*

- (1) *Let V be an irreducible representation of G over F . Then V is realizable over $\mathbb{F}_p(\chi_V)$ and $\text{End}_{F[G]}(V)$ is a field. In particular, the Schur index of V equals 1.*
- (2) *Let χ_1, \dots, χ_r be the irreducible characters of G over a splitting field of G of characteristic p . Then $\mathbb{F}_p(\chi_1, \dots, \chi_r)$ is a splitting field of G .*

Note that for G of exponent m , every $\chi(g)$ is a sum of m -th roots of unity. Thus Corollary 4.6.12 holds with the condition $\text{char}(F) = 0$ replaced by the weaker condition that $\text{char}(F) \nmid \#G$.

Proof. (1) Let $F_0 = F(\chi_V)$. Let U be an irreducible representation of G over F_0 such that V is an irreducible factor of U_F . By Wedderburn's little theorem, $\text{End}_{F_0[G]}(U)$ is a field. Let K_0/F_0 be a finite abelian extension of group Γ such that K_0 is a splitting field of G . The multiplicities of the irreducible factors of V_{K_0} are 1. Let W be one of them. Then $U_{K_0} \simeq \bigoplus_{\sigma \in \Gamma/H} W^{\sigma^{-1}}$, where H is the stabilizer of W . Moreover, $V_{FK_0} \simeq \bigoplus_{\sigma \in (\Gamma_0+H)/H} W^{\sigma^{-1}}$, where $\Gamma_0 = \text{im}(\text{Gal}(FK_0/F) \rightarrow \Gamma)$. Then the stabilizer of χ_V in Γ is $\Gamma_0 + H$. However, $F(\chi_V) = F_0 = K_0^\Gamma$. Thus $\Gamma = \Gamma_0 + H$ and $V \simeq U_F$. It follows that $\text{End}_{F[G]}(V) = \text{End}_{F_0[G]}(U) \otimes_F K$ is commutative.

(2) This follows from (1) and Corollary 4.3.4. \square

We state without proof the following partial improvement of Corollary 4.4.9.

Proposition 4.6.16. *Let G be a finite group and H a normal abelian subgroup. Let F be a splitting field of G with $\text{char}(F) \nmid \#G$. Then for every irreducible representation V of G , $\dim_F(V) \mid (G : H)$.*

In the case $\text{char}(F) = 0$, the proof uses algebra integers [S2, §8.1]. For $\text{char}(F) > 0$, one lifts to characteristic zero [S2, §15.5].

4.7 Tannaka duality

Let F be a field and G a group. Let $\Phi: \mathbf{Rep}_F(G) \rightarrow \mathbf{Vect}_F$ be the forgetful functor carrying (V, ρ) to V . We let $\text{Aut}^\otimes(\Phi) < \text{Aut}(\Phi)$ denote the subgroup consisting of natural automorphisms $\phi: \Phi \xrightarrow{\sim} \Phi$ such that for each pair of objects V and W in $\mathbf{Rep}_F(G)$, $\phi_{V \otimes W} = \phi_V \otimes \phi_W$.

Theorem 4.7.1 (Tannaka). *The map $T: G \rightarrow \text{Aut}^\otimes(\Phi)$ given by $T(g)_{(V, \rho)} = \rho(g): V \rightarrow V$ is a group isomorphism.*

This is a linear analogue of Remark 1.17.27.

Proposition 4.7.2. *Let R be a ring and $\Phi: R\text{-Mod} \rightarrow \mathbf{Ab}$ the forgetful functor. Then we have an isomorphism of rings*

$$R \simeq \text{End}(\Phi), \quad r \mapsto T(r), \quad S(\phi) := \phi_R(1) \leftarrow \phi,$$

where $T(r)_M: M \rightarrow M$ is given by r .

Proof. It is clear that $ST = \text{id}$. Let us check $TS = \text{id}$. Let $\phi \in \text{End}(\Phi)$. For every object M of $R\text{-Mod}$ and every $m \in M$, let $f: R \rightarrow M$ be the homomorphism carrying 1 to m . Then $\phi_M(m) = \phi_M(f(1)) = \phi_R(1)m = TS(\phi)_M(m)$. \square

Lemma 4.7.3. *Let $\Delta: F[G] \rightarrow F[G] \otimes_F F[G]$ be the F -linear map given by g to $g \otimes g$ for $g \in G$. Let $x \in F[G]$ be such that $\Delta(x) = x \otimes x$. Then $x = 0$ or $x \in G$.*

Proof. Let $x = \sum_{g \in G} a_g g$. Then $\sum_{g \in G} a_g g \otimes g = \Delta(x) = x \otimes x = \sum_{g, h \in G} a_g a_h g \otimes h$. Then $a_g = a_g^2 a_g a_h = 0$ for $g \neq h$. Thus $a_g = 0$ or 1 and there exists at most one g with $a_g \neq 0$. \square

Proof of Theorem 4.7.1. Let $\phi \in \text{Aut}^\otimes(\Phi)$. Note that $\Delta: \text{reg} \rightarrow \text{reg} \otimes \text{reg}$ is a morphism in $\mathbf{Rep}_F(G)$. Thus

$$\Delta(\phi_{\text{reg}}(1)) = \phi_{\text{reg} \otimes \text{reg}}(\Delta(1)) = (\phi_{\text{reg}} \otimes \phi_{\text{reg}})(1 \otimes 1) = \phi_{\text{reg}}(1) \otimes \phi_{\text{reg}}(1).$$

By the lemma, it follows that $\phi_{\text{reg}}(1) \in G$. We claim that $S: \phi \mapsto \phi_{\text{reg}}(1)$ is an inverse of T . It is clear that $ST = \text{id}_G$. That $TS = \text{id}$ follows from Proposition 4.7.2. \square

Remark 4.7.4. (1) For F separably closed and G finite, one can show that $\mathbf{Rep}_F(G)$, regarded as a symmetric monoidal category, determines G up to isomorphism [DM, Theorem 3.2].

- (2) The F -algebra $F[G]$ does *not* determine G . For example, for G finite abelian, one can only recover $\#G$ from the \mathbb{C} -algebra $\mathbb{C}[G] \simeq \mathbb{C}^{\#G}$.
- (3) The category $R\text{-Mod}$ does *not* determine the ring R . Two rings R and S are said to be *Morita equivalent* if the categories $R\text{-Mod}$ and $S\text{-Mod}$ are equivalent. For example, R and $M_n(R)$ are Morita equivalent. Morita gave criteria for such equivalences of categories. See [L1, §18].
